> enough.
So do I.It has been in the cellar of a friend who has died now.I made a stub of RG174 and connected it to my dummy in this way I'd connect it to the dipole.Then I cut it off and short-circuited it until the swr was 1,1.The crazy thing was,that the length is now 30 cm,and not 50 cm regarding the k factor,as a quarter-wave stub should be.

Tom, DL7JSK wrote:
"---the length is now 30 cm, and not 50 cm regarding the k factor as a quarter-wave stub should be."

A quarter wave at 2 meters is about 50 cm but the velocity factor in most coax is about 2/3. So, 30 cm for a short-circuit stub which behaves as a parallel resonant circuit, sounds about right.

Best regards, Richard Harrison, KB5WZI

No, only the bad news gets publicized. I think the odds are about equal
in getting ripped off when buying used gear most anywhere...here on
Usenet, Hamfests, ebay, 'widder' auctions or wherever. Online stuff has
the disadvantage that you can't see it personally but also has the
advantage of being your hamfest 24/7.
Just like used cars, you have to assume its not as good as advertised
and maybe there's something wrong with it that either the seller is not
saying or has no clue. Given that risk, one bids or pays accordingly.
A few questions to the seller often sorts the wheat from the
chaff...just like in any venue.

Reg wrote:
"Dissipationless resistance is certainly abused on this newsgroup. Why the description was ever invented I can`t imagine."

Reg feigns ignorance for his own amusement I suppose. Reg knows the definition of resistance is a ratio of voltage to current when these are in-phase.

A resistor, on the other hand, is a resistance device which converts electrical energy to heat energy.

Some authors carelessly confuse resistance with the resistor. Because of a tendency to assume a resistance to be a resistor, the term "dissipationless resistor" is needed.

Most radio people know power is not equally shared between a 50-ohm transmission-line and its 50-ohm load. Why? The 50 ohms of the transmission-line is dissipationless resistance.

Likewise, a Class-C amplifier can be perfectly matched to a load if necessary and still dissipate considerably less than its matched load does. Why? A good part of the internal resistance of the Class-C amplifier is dissipationless resistance.

Dissipationless resistance doesn`t store energy as reactance does, but limits energy movement without producing loss.

The only possible effect is a slight lowering of the resonant frequency of the antenna. Varnish acts like a dielectric in series with the field between the two halves of the antenna.

The effect is so slight though, I doubt you would even notice it unless you compared two identical antennas, one with and one without varnish.

May I offer some unsolicited advice? Move away from such a polluted area. You only get one set of lungs. Make 'em last.

The connection IS a short circuit at LOW frequencies. At the frequency
of operation, it appears to be a 50 ohm resistor. The reason why is a
bit complicated, but a book on antennas and transmission lines should
help you to understand. It has to do with the time it takes for the
current to travel around the "J".

It's pretty close. For a dipole at 144 mhz, which shows an SWR of 1.4:1, as in an appx 70 ohm feed, I calculate the stub should be 19.02 cm below the feedpoint, and a stub length of 27.25 cm. The stub end would be closed. But I doubt I would bother with one myself. 1.4:1 is good enough. Besides, he can adjust the antenna if needed to get a good match. MK

Yeah, I suppose it's inevitable, but I for one will not appreciate an electronic QSL as much as I do the old-style postcard kind. I like seeing the pictures chosen by the DX, I like it when I get a card with a hand-written message on it (yeah, that's pretty rare) and I like getting stamps from the DX country on their envelope.

Sure, lots of people now just print out a stick-on label for their card. Lots of people just use those generic callsign-and-qso-info cards. Lots of cards don't come with exotic stamps, since they arrived via the manager, or were metered instead of stamped. Still, I come home every day and the first thing I do is check the mailbox for QSL cards. The electronic ones just won't have the same thrill.

You can use anything that keeps the wires from touching. I actually prefer small egg insulators, as they permit much shorter connections from the feedline to the elements. If you are stuck on dogbone, check with the Wireman or any of the other cable and antenna vendors listed in the ham magazines or on the general web sites.

Depends on the judge. There was a case in Md 20+ years ago where a CBr
was taken to court over his vertical. The judge cited an opinion in
which racial CC&Rs had been invalidated which said that CC&Rs' only
purpose was to protect property values and, since the HOA bringing that
suit hadn't proven that the dude's antenna lowered their property
values, they had no case. Obviously, YMMV from court to court but I'd
think that defense has been strengthened by recent federal laws
specifically exempting TV antennas. Recommend getting a legal opinion

Reg wrote:
"What is the formula for calculating the dissipationless resistance of a Class-C triode amplifier?"

Terman says that cut and try may be the best way to optimize Class-C amplifier design. That is, tweaking after one has schemed to make best use of the output devices` maximum capabilities.

Dissipationless resistance is not addressed. It is an inverse function of the conduction angle which affects other characteristics of the amplifier such as harmonic generation. Efficiency is addressed.

Efficiency is output over input. The d-c input and r-f output are easily measured.

The designer wants best utilization of the output devices, high output power, and efficiency. If the Class-C amplifier were lossless, all its internal resistance would be lossless and it would be 100% efficient. 70% isn`t bad and is better than 50% which would be the limit absent the lossless resistance.

Best regards, Richard Harrison, KB5WZI

Drink........ Can't comment on the performance of the SC7900A per se. I have 2 Diamond NR77HA dual banders, one on my S-10 (mag mount) and other on a Pont. TransSport. Never had a problem with the fold over mechanism or their performance in general. I did have a problem with the unit on the TransSport when I have the roof top carrier installed. The ant. is mounted at the left rear of the roof and air flow around the carrier would cause enough lift the ant. would fold over. Often would occur when a semi passed in opposite direction. I fixed with a piece of fishing line to guy the ant. to the roof rack.
The NR77HA is 39" overall length and I have to fold over to get into our 7 ft. garage door opening.

2996. antenna *in* chimney?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-11 16:54:56 UTC
From: tucansam@whodis.org
Message-ID: <a48t0v$78r$1@news.panix.com>
Source record: 148885

Hi all,

I live in an apartment with a "no external antennas" rule. We have a fireplace that we never use.

Is it possible to mount an antenna *in* the chimnet, and get good results?

The chimney is brick, with a metal mesh top. I know both of these facts will deminish its ability, but would it be better (being higher) than simply mounting the antenna hanging from the ceiling inside?

Thanks.

It might have a 25-ohm resistance. There is no way your SWR meter will tell
you which is which.

I once read of a ham who, running an amp to balun-fed tribander, was well into a SSB contest when a passerby rapped on his door and announced that the ham's antenna was on fire. It was the balun, blazing away. I imagine that balun was feeling a bit abused.

Depends on the type of antenna and your definition of good. But it's lots
better than no antenna...

>

As long as you don't forget, and light the fireplace... :>) And if done
right, it could be pretty covert, which might come in handy if you happen
to take out the phones or televisions in the complex...

If your MFJ 259 says it's 100 ohms then it is 100 ohms. You don't need an
SWR meter when you can measure R and X directly. What use can you make of
the SWR reading ?

Good DX

tucansam,
You will get some results, but nothing like it being
out side. It's probably the same, or slightly better than
the antenna being in-doors, maybe.
I think I'd like to see how you get the antenna into
the chimney! From the bottom, the antenna better be very
flexible. From the top, your neighbors will see you. (LOL)

Source record: 148896

Hello Tazanator,
As long as one's transmitter can tolerate a 2:1 vswr there is nothing "wrong" or "bad" about that value. It is not ideal (1:1) ..but nothing is in the "real-world".

As far as performance goes no one receiving you would be able to tell any signal strength difference if you were somehow able to switch back-and-forth between 1:1 and 2:1. With a 2:1 vswr nearly 90% of one's transmitter power is being radiated....

It takes a change in power of x4 to see a 1 s-unit increase in field strength. The difference between 90% radiated and 100% radiated in this scenario is miniscule at best.

If you - must - see a 1:1 then fine business..trim and adjust till you see it.... some people can't sleep at night if their vswr is above 1:1 !! They ought to quit fussing, bone-up on transmission line theory, and start enjoying their radios!

Well sad to say, Ham radio even for emergencies is becoming a thing of the past. Newer technologies are here and coming, that Federal, State and local emergency services are using, that can be setup and be on the air in minutes. I like CW, but I can't think of any scenario where it would be absolutly needed, abeit nuclear war, where someone needs it. (In which case I for one, am not going to hang a dipole in a tre and pound a key..;P) or your homebrewing a transmitter from scratch on a desert island to call for coffee. Again, not downing CW, I enjoy CW, just technology has changed so much with satellite, microwave, etc. I don't think even alot of newer people are interested in it as they were 20 years ago. I think CW will be here as long as there is ham radio if nothing else than tradition. But there is a different people today coming in expecting different things like satellite, microwave, computer radio interface, etc. Not that thats bad, just times change.. Even homebrewing is becoming more of a "specialty". Mass production made alot of stuff in ham radio cheaper to buy than make. I personally like to make as much of my gear that I can. Also like to restore old receivers and transmitters, but the guys who do it are getting fewer. Lots of the old Elmers are SK or too old to teach anymore. For guys just coming in the hobby and even for guys like myself, you could learn alot from the old timers but not enough people are learning to take the place of the ones gone. I mostly grew up just when the old tube gear was going to solid state so right off I was handicapped with the old stuff not knowing anything or finding anyone that knew anyting about it. Most of the new gear is "Plug and Pray", fry a board you throw it out and get a new one, never understanding how it works.. I read my butt off on every book I could find. I really believe I would be much more knowledagble if I had some experienced Elmers around to show me some things. But I did ok considering I was learning a technology that most guys had forgotten. (probably alot of you guys were in the same boat..) I think mass production of gear and the loss of good Elmers have seriously crippled new people as far as learning. Shame really. Nothing like firing up an old rig and making a contact or hearing a station on a radio you repaired or made yourself. The thrill of something you made or repaired is something that few hams experience today. This is what I really think is missing today. Enough ranting..Thanks for reading..

I think Reg has confused the MFJ-259 with the MFJ-259B. I
don't believe the
259 can measure Reactance, X.

============================

Thanks Irv for the correction.

Even if the instrument does not measure X, and only measures Z, I think
the SWR meter is still superfluous.

When frequency is varied for minimum line input Z as indicated by the meter,
for practical purposes three conditions are simultaneously satisfied -

(1) X = 0
(2) Since X = 0, R = Z
(3) SWR is also a minimum = Z/Zo or Zo/Z.

With the ordinary transmitter, if Z is in the range 33 to 75 there's nothing
to worry about.

Just thought Id post a silly one!- Actually ..those nylon dog bones are very tough and durable and come in sizes which resemble end insulators of antennas.
My dachshund hardly touches the ones I bought him..he much jprefers the rawhide ones he can digest..so I may clean up the others and put them in my junkbox..73 Earl VE3AB

As usual, the pundits reply without all the information necessary to give a
useful answer.

WHAT BANDS??????

For high HF and low VHF, I would look at replacing the mesh chimney cap with
a visually identical unit with the antenna integrated into it.

The question you asked is: " but would it be better (being higher) than
simply mounting the antenna hanging from the ceiling inside?"
and the straightforward answer to that is most likely yes, unless that
chimney is actually a metal smokepipe, which raises other possibilities for
HF.

While trying to "improve" the circuit of my MFJ-901B tuner, I think I may have fouled it up. I attempted to add a movable tap, using a short length of wire and an alligator clip, by removing the lead to one of the tap points I never use (tap 'K'). I unsoldered the two caps, in order to get easy access, and now that everything is back together, I can't get a match, or anything like it (off the scale SWR readings) on any frequency, any band.

Nothing else is changed, and I have ruled out the rig and the coax jumper between the rig and tuner by testing on a dummy load. The caps check good, nothing is shorted to ground there. I am a little confused about how to check the coil and coil switch, though. There is a lead from between the two caps to the top of the coil, and then 12 taps spaced along the coil, each running to a lug on the switch. For the time being I have removed the jumper I had added and not reinstalled the connection between the coil and switch for position 'K'. I used mimimal heat when soldering/unsoldering, and there is no apparent heat damage to the switch, so I am puzzled what could be wrong.

I did remove the factory supplied 4:1 balun, and have not reinstalled it. I am presently using the "wire" and "ground" lugs to connected to a ladderline fed V (the system works OK like that, out of balance maybe, but I plan to add a coax-choke-balun once I get the tuner working again). Like I said, all was well till this misguided attemtp on my part to improve things, which were perfectly workable to begin with!. Please help me fix my tuner so I can get back on the air! Thanks!

If I understand correctly, you'd fold over the antenna so the canoe could rest on the roll bar. Would that mean the antenna would be horizontal when the canoe was mounted? If that's the case, I'd assume you wouldn't be using your radio with the ant. folded. You might try mounting the ant. to one side so the canoe and ant. could co-exist. That's why I mounted the ant. on the Trans Sport at the LR so I could use a roof top carrier when we camped. It works fine.
Do you have any flat spots to use a mag. mount? You could move the ant. to jeep hood when the canoe was on top.
Another consideration is what are the relative dimensions of the antenna and where it folds. For example my 39" ant. folds at 33" so there is a 6" stub that might interfer with a canoe seat. You'd need to check it out.
Your best bet is to put the canoe in place and mock up an ant. and see what works best.

I have owned the diamond SG7900A for over a year. I have it mounted on the trunk lip of my Grand AM using diamond's K400 lip mount. This mount is excellent as well as the antenna. Please make sure you buy a good mount. I made the mistake of saving 25 bucks by purchasing an MFJ mount for my mini-van instead of a Diamond. Within two months the main screw used to adjust vertical alignment was rusted and would barely turn. It has been over a year now and the Diamond mount on the Grand AM is still rust free including all screws and misc. hardware.

I have no complaints with the antenna, it works great. The only thing I will caution you about your proposed installation is that you may very well not want the antenna on your roof rack. I guarantee that you will bend the antenna eventually.

I have the slightly smaller Diamond SG7500 on my Chrysler Mini-Van mounted at the top of the lift gate. I can't tell you how many times this antenna has hit the overhang at the Bank, Micky Ds, Garage, Etc (Still going strong, testament to quality). This antenna will bend if subjected to enough stress. I also would not want to travel with the antenna folded over. The antenna will begin to emulate a small helicopter if you get my drift. This feature is VERY nice for making it inside the occasional parking ramp, but it will get annoying if you need to constantly be hopping out to flip down the antenna.

I love my Diamond antennas both mobile and base. They are built of quality materials that don't rust or come loose with time and abuse. I can attest to this. Living in Wisconsin and having lots of road salt and grime will prove the rust worthiness of any antenna. You will be satisfied to. I guarantee it.

Matt - KB9VSE

N4DAV wrote:
"I want to use two UHF repeaters on one antenna, spaced about 20 MHz apart."

The pass / reject circuits are much more satisfactorily explained with diagrams, pictures etc. A book will be a big help. On hand is Ken Sessions, Jr`s ""Radio Amateur`s F-M Repeater Handbook". Elsewhere I have a couple more books with almost identical information, but different authors.

These books describe the hybrid loops and cavities used for diplexing. The books credit Gil Boelke, W2EUP for describing the systems commonly used by amateurs.

Because the signal level of the transmitters is so enormous as compared with the tiny level with which the receivers must operate, the signal separations provided by the signal separation devices must be extremely good.

If I were building T / R sets, I`d build in magnetic separators. But they are very expensive. So for a one-off construcion, I`d be tempted to use separate dipoles. One for receivers, probably using a multicoupler to avoid interaction between receivers. Another antenna would be used for the transmitters, probably using a hybrid or hybrids to avoid interaction between the transmitters.

I would probably stack vertically polarized antennas one over the other so that they would be put in each other`s nulls to minimize coupling between antennas. Then I`d work on further minimizing coupling between all pieces of the system.

Best regards, Richard Harrison, KB5WZI

I remember the times when a reputable dealer (or ham) would sell a
transceiver to a unlicensed person. They would then tutor the person
in the code and enough theory to get their novice license.

Of course, that was when a Novice was limited to crystals and 75 watts.

Gary,

Are you talking about the Kirk Antennas? Kirk was W8FYR and he sold out to
a firm in Connecticut (Viking).
I don't think he ever made a tri-bander tho. Helicoidal he called them. I
had a big 5 el 20 that I sold to a W9
years ago. I picked up another from a local silent key which I gave to K9AY
as I had no manual. He used 3 or 4" fiberglass booms and the elements were
fiberglass with copper tape for the elements.

I hered about a device called antenna tester it is just a
RF-generator plus a SWR measurements .
it is for antenna installation .
i dont know waht is its benifit for antenna installation .
i mean i have static frequency channels(i.e TV channels) and of course
static antenna lenght (i.e fixed)
then what may i gain with that tester.
another question:
i know that a receiving antenna must be in the order of half the
wavelength
. is that apply for a transimitting one ?

Yes, Potato Gun. Very popular item with the teenagers in my area, Phoenix.

A 2-3 foot length of ABS pipe, a little combustable gas, a Gas Grill
ignition unit, and some potatoes. Great for launching some spuds into
the desert or the lake. If you have teenagers and you suddenly notice
that the ignition button from your Gas Grill is missing, you can bet
there is a potato gun in the makings.

My thanks to everyone who replied to my post for your practical descriptions of what has worked for you in the past. I'm going to try a number of them out over the next month and I'll report back how they worked. Again, thanks for the overwhelming response of pracical advice. You gave more advice in your posts than I have ever seen even in the books and magazine articles covering the subject! I think that is what makes this NG fantastic! I'm impressed!

73,

Greg, N6GK/m
"Greg Knapp" <gknapp@freshrain.org> wrote in message
news:iXd98.810$1F2.18606@sea-read.news.verio.net...
Could you share your experience with me? I have tons of ignition and other types of noise (S-8 average on the IC-706) coming from my antenna (a screwdriver on a foldover bumper hitch mount), which is located about a foot or two from the tailpipe on my new Toyota Sienna van, making it difficult, and certainly not enjoyable, to work the HF bands.

If I turn off the engine, all the noise disappears. If I disconnect the antenna, again it all disappears, so I know it's coming from the engine and not coming through the dc power or other control lines).

So, I figure it's most likely the tail pipe, being so close to the antenna, and tons of mobile books say to ground the tail pipe in one or more places, or move the antenna. I can't move the antenna, but I don't have a clue how to ground it.

So, I need some advice. How do you actually ground the tail pipe? Do you drill holes in it to attach some copper grounding strap with self-taping screws? Do you hose clamps to clamp a piece of copper grounding strap to it? Do you scrape it to bear metal and then apply that non-oxidize stuff ("butter") they use on beams to keep the corrosion down and the conductivity up? How do you connect the grounding strap to the underchasis of the car...drill more holes? How many straps does it usually take? How long can the straps be and still be effective? How do you seal the connections so the rain, wet, mud, etc., under the car doesn't make short work of it?

In other words, I'm not very mechanically inclined and really getting too old to climb all over under the car...how do I do this as simply, yet effectively as possible? Any advice is appreciated. Is there a commercial radio place that does noise reduction for a reasonable price in the SF Bay area?

Thanks,

Greg, N6GK

Don't scrap your ARES nets just yet. If 9-11 is any indication the reverse may be true, at least for a while. Many agencies had come to rely on cell phones (some had even scrapped their radios) only to find the cell net hopelessly jammed when everybody and their dog tried to use it at once. That's why officials are scrambling to change the system so they can cut off "non-essential users" (ie, us); but the telcos are saying "prohibitively expensive".

> help?
>

The 'nut' is keeping the xmtrs from desensing the rcvrs. As you know most repeaters simultaniously xmit and rcv only 5MHz apart on the same antenna useing very sharp cavity-type band pass filters (duplexers). My old GE Mastr II has 2 "cans" in series keeping the xmit'd signal out of the rcvr plus a third on the xmtr to keep it in band. The output of the xmit 'can' and the input to the rcv cans are cabled to the antenna via a simple N-connector "T". I'd think you could add another repeater (xmt/rcv pair) so long as the freq's were far enough apart for the filters to handle. A directional coupler might help prevent rcvr desensing even more and I've heard of stacking seperate antennae vertically by putting the xmit antenna inside a non-metallic section of mast with the rcv antenna and radials atop it to farther improve xmit-to-rcv isolation but I've never tried it myself.

I have to agree with you. I am a new ham, probably on the younger end of the curve, manage
an emerging technology and am heavily involved in new cutting edge technology. But, in
this area, I agree physical, hand-signed cards are superior to eQSLs; at least for me anyway.
Not being a fan of eQSL doesn't make one a Luddite.

Great antennas, by the way. I have the 80/40/20/17/12 version and it
works just as advertised, at 1500 watts, with no problem. The perfect
companion to a triband beam. .

Bandwidth is reduced compared to a full size dipole of course, but
efficiency is very good. Took about an hour's tweaking to get the
resonance where I wanted it on all bands

The usual disclaimers apply - just a satisfied customer.

: WHAT BANDS??????

Initially, only ATC bands. I live close enough to Oakland Center and SFO to pickup communications from aircraft at or above about 6000 ft AGL, but of course can get no tower communications at all. I can get these signals with my cheapo RatShack handheld scanner, and would like to do something in terms on an antenna so I could invest in a nicer base unit and pick up tower traffic from these airports as well.

Eventually I'd like to be able to work some of the more popular ham bands, but this would only be after tax time, assuming I can pick up a decent base station to replace my 2 meter handheld after refund time :)

: simply mounting the antenna hanging from the ceiling inside?"
: and the straightforward answer to that is most likely yes, unless that
: chimney is actually a metal smokepipe, which raises other possibilities for
: HF.

I believe that, indeed, the chimney is a metal smokepipe, simply encased in brick to make it look nice. I need to crawl in my fireplace with a flashlight to confirm. The place was built in 1983, and its fireplace has been used *once*, so there shouldn't be too much trouble affixing some mounts for antennas (dirt-wise, I mean).

The latest version of OE doesn't have a <reply all> button, or at least mine
doesn't. Netscape OTOH has it right next to the reply and it's really easy
to hit the wrong button and not know it till you hit send.

This is a rather short thread and because of that I know to what you refer,

Actually, it's gone the other way. 20+ years ago, CC&Rs were not so common. Neither was cable TV. TV and other antennas were considered normal appurtenances to a home back then.

Today most new tract construction has lots of CC&Rs and buried utilities, cable TV is all but universal and more people have Gladys Kravitz syndrome. Not to mention RF exposure.

The pizza dish TV folks had to go to the Supremes to get their exemption!

>Recommend getting a legal opinion
> from a local lawyer after researching

Excellent advice!

But make sure it's a real estate attorney, and that he/she knows exactly what you are talking about.

The long-term solution for ham radio is for all of us to get Congress to mandate an exemption. FCC isn't going to do a thing without a congressional mandate.

But I stand by my original point: Negating some CC&Rs does not negate all of them.

> hi..... GW0GVQ

Would depend on if you want it to actually be resonant on 160m, and
how far out from center each coil is. The farther out from center the
coil, the better the current distribution, but the more coil turns
needed. And more coil loss also.
The increase in current distribution will usually outweigh the coil
loss up to a point. Anyway, if you want to get the most bang for the
coil, put them at the center of the antenna at the feedpoint. You
would just have to experiment to see how much wire it took to resonate
the antenna . If you are feeding with ladder line, it doesn't have to
be exactly resonant. Actually, to do what you are doing, which is try
to run all bands with one antenna, I'd use a ladder line fed 80m
dipole, 60 ft a side, 120 ft total. For 160m, I'd short the ladder
line together and run as a shack/tuner fed T vertical. I wouldn't use
any coils in the antenna. You would probably have better overall
performance on most of the bands. 80m should be a good bit better. 40m
will be ok as two half waves in phase. 20m would be an X pattern which
should still do ok. MK

Hi Will,

Then it may be due to the wire with the clip being too stiff and
levering the contact open (when you clip to the coil). Not unusual at
all for marginal switches. This would answer that particular switch
setting acting odd, but not the unit generally. DC continuity tests
for opens and closes should be fairly straightforward.

Another point may be that the flying lead you added wanders too close
to ground (without actually shorting - but enough - this is a long
shot however).

Source record: 148749

Just run a wire up the chimney, or along the outside wall of the house. and
it will very likely do reasonable well.

Just get the top end as high as possible above surrounding structures. If
you are allowed to have a TV antenna mounted on the chimney then load the
transmitter into the coax TV feedline. (Disconnect the TV while
transmitting).

The lower frequencies, 1.8 to 4 Mhz are much less likely to cause
interference to other equipment. Suck it and see. You won't do much harm.

Use the domestic plumbing system, hot, cold, central heating as a ground.
One or two big alligator clips are useful.

Nothing ventured, nothing gained !

Cecil's antenna works exactly as he says. I have built several configurations based on his idea and measured all with my MFJ259B. They all check out as promised in his description and as modelled by EZNEC. I worked over a thousand QSOs worldwide this past weekend in a RTTY contest with his antenna and no antenna tuner.

Save your antenna tuner money.

Get a friend to help - measure your signal strength on his radio both
in the attic and inside the chimney. If your strength is down only a
bit, just use an amp to make up for it. Your received strength might
be down also, but may work out OK anyway.

Jerry W4UK

3056. MA5V mini review followup

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-12 20:19:57 UTC
From: Javier Henderson <javier@KJSL.COM>
Message-ID: <86r8nqxxjm.fsf@grumman.kjsl.com>
Source record: 148742

I posted the MA5V mini review recently. This is a follow up after a few days of using it...

I'm in California's central coast. The baseline QRN seems to be about S3 on the average. I've been having no problems hearing stations from pretty much everywhere.

Transmitting, I see a VSWR of 2:1 or less across all the bands, with close to 1:1 towards to center of each band.

That is all.

73,

-jav w6vms

Tucan Sam wrote:
"Is it possible to mount an antenna in the chimney and get good results?"

Sam`s interest seems to now be in air traffic control radio reception between about 108 MHz and 140 MHz.

Lambda is about 2.8 meters at the low end of that frequency range. !/4-wave is about 0.7 meters. That`s about 2.3 feet. This should be shortened by about 5% for end effect to give about 26 inches.

Sam could make a coaxial antenna from coax and support it in a rigid plastic tube. RG-8 or almost any 50 or 75-ohm coax would do. Just skin back about 26 inches of the braid, keeping it intact, and fold it back over the vinyl sheath to create a dipole from the exposed insulated center conductor and the folded back outer conductor over the vinyl sheath.

Home Depot could supply the plastic pipe or conduit that would just accommodate the coax. These plastic pipes can be strung together to extend beyond Sam`s chimney so that at least the plastic pipe encased bared center conductor extends outside the chimney`s lid.

If the added height gives sam a line-of-sight path to a control tower, it may be worth the effort.

Glue a plastic cap on the plastic pipe to keep out moisture and use camouflage paint to hide the salient plastic to some extent.

Best regards, Richard Harrison, KB5WZI

He could do this if he didn't give a damn for bandwidth. This band is
almost 20% wide.

If you hadn't read his post that he thought the pipe up the middle was metal
and that the spark arrestor on the top was metal, this might work.

>

> > Well sad to say, Ham radio even for emergencies
> > is becoming a thing of the past. Newer technologies
> > are here....

Well, maybe...

One government / military program ("newer technology") is called JTRS (Joint Tactical Radio System - 'jitters') **.

S'posed to be able to replace almost all other government / military radios by "simply" being able to download the "waveform" (<eyes rolling skyward...>) into the software radio and popping up on almost any band, and in any mode, with any encryption and/or protocol. S'posed to cover from sub-HF to XX GHz - where 'XX' is getting more and more ambitious (if the trend continues, by next year it will cover DC to daylight). S'posed to ensure interoperability since ya can just download the "waveform". Not quite sure how much power this puppy is s'posed to emit... Not sure if it will be full duplex or not... Not sure if it will fit...

Obviously (to anyone that can spell the plural of "antenna") they are 'writing cheques' that antenna technology (now, or in the foreseeable future) 'can't cash'.

Obviously, interoperability is going to be extremely limited by the installed antennas on any particular air / land / sea vehicle.

WTB: multiport antenna covering 2 MHz to 2 GHz (or even much higher), continuous coverage over all government (all levels), military and civilian frequency bands. Must provide decent gain and complete hemisphere coverage. Prefer switchable linear and RHC polarization as well as multiple null steering. Other requirements available upon request.

What we need here is a "Joint Tactical ANTENNA System" to match the capabilities and imaginations of the JTRS spec. writers. Perhaps someone will develop some sort of fractal, super-conducting, cross-field, miracle antenna that simply plugs into any regular outlet.

Oh well, I wonder if there is actually a small but rational program hidden behind the marketing mush (there could be...). Perhaps the glory is in the details. But I really wonder why they want to replace radio developers with software developers...

All the above is very much just My Humble Opinion.

Why don't you just contact Sinclair or another manufacturer, specify the repeater
pairs, and see what they reccomend? If you are going to use a commercial and
ham repeater on the same antenna, with 20 MHz seperation, you will have to
do some serious research on finding an antenna with the required bandwidth.
It won't be cheap.

Someday we will probably all communicate by mental telepathy and won't need any other equipment. In the meantime, when the power and phone lines are down, and the fire sweeping up the mountain takes out all the repeaters, it is still the hams today who provide the emergency communication when the going get tough.

I had to do a talk on amateur radio to a men's club recently, and one of the things I focused on was emergency communications. When I started researching everything we (amateur's) have done in that area over the past 75 years or so I was really amazed. The fire in Los Alamos in May 2000 is a prime example where the hams provided essentially all of the communications for days. And that was a government installation.

Yes, the day will come when communications have advanced to the point where we won't be as necessary as we are now. For the time being, join your local ARES/RACES and be ready to do your part.

Thanks, Jerry. The only fly in the ointment is when the 450 ohm SWR is less than 4.5:1. I'm going to build a transformer circuit that will step 120 ohms (for instance) down to 60 ohms.

Question for the gurus: For an RF transformer, would an open air coil be better than a ferrite transformer or a powdered iron transformer?

Jim Weir wrote:
"118 to 137."

My Panasonic monitor receiver tunes 108 MHz to 140 MHz. Sam didn`t tell us the limits of the band he would like to receive. My arbitrary choice might be as cood as Jim`s.

Jim Weir wrote:
"22 inches is the geometric center of the band."

My experience with receiving antennas is good when they are slightly too long. Standing waves and inefficiency are usually of little concern with receiving antennas such as this.

Jim Weir wrote:
"If you hadn`t read his post that he thought the pipe up the middle was metal and that the arrestor on the top was metal, this might work."

Sam may find an angled route between the chimney and its cap for extension of his antenna. There would be an escape path for smoke. The antenna would not operate so well within a metal pipe or so well in all directions alongside a metal pipe.

The plastic pipe is a suggested support of a coaxial antenna to place it in a hopefully clear position to receive signals. The chimney may give lateral mechanical support to an otherwise flimsy plastic pipe so that its strength in compression may be used to hold the antenna up.

A coaxial antenna can be a good performer. I`ve used them several times with good results.

Best regards, Richard Harrison, KB5WZI

No kidding, I spent a month in WV last summer during the disaster
relief effort after the flooding they had. Using the VHF radios the
Red Cross has in their Emergency Response Vehicles was a challenge, we
definately could have used some more hams to facilitate better
communication.

And I ran into that again in NYC, I spent the majority of 3 months
there with the Red Cross, the cell phone they issued me was pi$$ing me
off. Too many people in this line of work are relying too much on cell
phones, this is why I took my amateur test last saturday (and passed),
and am now working on getting the code down for my general ticket.

Victor wrote:
"I am building a Jpole antenna---."

The "J" antenna is a 1/2-wave vertical radiator resting on a 1/4-wave short-circuited stub used as a matching section. The feedpoint may be slid up or down on the 1/4-wave matching section to find a match. A wide variety of feedlines can be accommodated.

The shorted bottom of the "J" can be directly grounded for lightning protection. Coax is often directly used with the "J" antenna.

Victor shows a nonconductive support for his "J" antenna, but insulation at this point is not required as the bottom can be grounded.

My recent experience with a "J" antenna was the 2-meter version made of twinlead supplied by MFJ. It was light, inexpensive, and worked well.

Best regards, Richard Harrison, KB5WZI

3073. IC-706 tuning control

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-13 03:33:55 UTC
From: CAM <Cecil.A.Moore@IEEE.org>
Message-ID: <3C69DEA3.DA5B5451@IEEE.org>
Source record: 148761

I just got through breadboarding what I consider to be a really slick
way to use the IC-706 tuning control with a screwdriver. Here's the
schematic:

```
Wires to the screwdriver motor +------+
-------------+---------------------------------------->|motor |
-------------|--------+------------------------------->| |
| | +------+
anode anode
1N4001 1N4001 +12---(10k)---------+ Tstr
cathode cathode |
| | C|---+ Tkey
+--------+------------------(10k)--+--|B 2N2222
| E|--+
(10k) |
| |
Gnd Gnd
```

When the tune switch supplies power to the screwdriver motor, the
2N222 turns on grounding Tkey and Tstr. As long as the screwdriver
tune switch is engaged, the IC-706 outputs 10 watts in CW mode.
When tuning has been completed and the tune switch disengaged,
the IC-706 returns to SSB mode (or the previous mode if not SSB).
I haven't seen this described anywhere and I like it best.
Two diodes, three resistors, and one 2N222 transistor.

Plez Help
Im looking for a program that I can use to design my own type of antennas from directional to omidirectional for different Frequency ranges of my CB,TV & Scanner that would give the length of the Boom ,Elements & Spacing type of Coax for each,best material to use (which I have some Alum. to use) and whatever else a person needs to know to build their own super homemade antennas. Also below is a list of manufacture spec. of 11meter cb antennas & rotors that I have and would scan [A Beem or Rotor Info] and e-mail for trade for the info I request above. TIA

In fact, we have two horses and a very quiet electric fence! I have a pile of the little black "egg" insulators but need the classic porcelain dogbone for a high power dipole.

I have used the hybrid yellow and black aluminum and polypro' 'hotwire' as a receiving antenna and it works great. I think it would work for QRP too but would quickly fry under more than 50 Watss.

The feedstore has also been a supplier for fiberglass rods used as temporary hotwire fenceposts!

The local large farm supply store went under last year. Now I need to drive to Red Bluff for the real exotic ham supplies.

Richard,

That is a good question, since it seems that *all* the switch positions read short to ground. I am concerned that I may not be using the proper technique to measure R, in this case. First, a quick sketch of this circuit. It is a T-network, of course, with the coax center of the input feeding the stator of the first cap, the rotors of the two caps connected in series, with a shunt connection between the two caps to the top of the coil. From that connection there are 12 taps on the coil to corresponding switch positions, and the case of the switch itself is grounded. I had thought that only the active lug/position should read close to 0 ohms, but now they all do. The caveat is that I never previously measured them, only once the problem arose. What I am saying is that I am too much of an electronic dummy to know if they *should all* normally read this way, or whether I am using my DMM correctly. Thanks, and thanks again if you can offer anymore insight.

(I do have the tuner working using a jumper to ground, bypassing the switch; works until I can find a suitable replacement switch or otherwise fix the circuit, but it is more than a little inconvenient to have to lift the cover off the tuner case and move the tap, replace the cover, apply power, dip the caps, and repeat as necessary, three times per band change or >100 KHz excursion sometimes!)

Hello Ian,
if you really do think that "real cards beat electronic cards any day of the week" then you really should stick with what you call "real cards". No one is forcing anybody to go with eQSL's

However I find the eQSL method to be much faster, much simpler, much cheaper, and a lot more fun. I have dealt with many "real cards" in my awards pursuits and in many instances had to spend "real money" in a losing effort that never yielded a card at all. I couldn't even get a qsl card from Mexico after 3 attempts each time with $$$ enclosed and SAE's. Finally the op there I was trying to get a card from emailed me and admitted the postal system was "wise" to the "real card" qsl game and was stealing from Hams all the time. With eQSL's I can "just say no" to unethical foreign postal workers once and for all.

I never liked the fact that to get a qso "confirmed" for an award had more to do with things completely out of my control (like postal workers stealing, and bad postal deliveries around the world, and DX ops that are in it for $$$ only) then it had to do with my station's performance level and / or my skill as an operator.

Furthermore I can get a DXCC credited qsl card (via eQSL) in a couple days for any - and - all qso's I make..even to the rarest-of-the-rare DXCC entities. This is the "new way" and the "much improved and long over-due better way". I am 100% on-board with eQSL and have been for months...it is fun and easy and it guarantees I get a card for my efforts and I don't have to depend on outside sources in foreign countries to cooperate so that I get the confirmation I am entitled to.

Those are my feelings.....maybe catch you on the bands one-of-these-days....

I agree Vito,
We need more people involved in ARES. We get perhaps one or two stations signing on in my area. I agree that ham radio would be good in an emergency. Cell phones in alot of areas are hit and miss, as in mine. In alot of the Western states such as mine, radio would be, in any manmade or natural disaster, the only way to communicate. And, we have the gear and can set up in a house or the field if needed should local emergency communications are knocked out.
What disturbs me is lack of participation in areas should an emergency occur. In alot of areas we're simply not ready. 73's Jim

Reg,

Is that not the common term in the UK? Come to think of it, it would be interesting to see a list of ham terms for the same things side by side, US and UK (e.g., "hamfest" v. "rally"). Yes, radio jargon is among the most colorful, interesting, and dare I say truly descriptive, i.e. accuracy and clarity as opposed to the vagueness and obfuscation of some other fields ("sales engineer," "sanitation technician.").

3080. Re: Loading Coils

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-13 07:24:31 UTC
From: remove_ok1sip@atlas.cz
Message-ID: <5f5159fa.0202122324.5bc2fce@posting.google.com>
Source record: 148768

Hi all,
theoretically, a whip is capacitive, if it is shorter than a quarter of wavelength. A resonant quarter-wavelength whip is purely resistive (low impedance at the feedpoint). A longer whip up to half of wavelength is inductive. A resonant half-wavelength whip is again purely resistive (high impedance at the feedpoint). And so on ... So a loading coil takes place at a whip shorter than 1/4 of wavelength or at whip 1/2 wavelength < length < 3/4 wavelenth, which is the case of the 5/8 wavelength one. The loading coil may be anywhere with the exception of the whip end. If it is right at the feedpoint, it has the smallest value, but the antenna has the least efficiency. Moving the coil towards the end increases both the efficiency and the necessary inductance, provided that you keep the coil losses on the same level (thicker wire etc.).
If you put two whips horizontally, feedpoints close each to the other and pointing in opposite directions, you get a dipole. The impedance characteristics of both halves still apply.
I recommend you to download the VE3ERP's HamCalc. It provides calculations both for whip matching and for a center-loaded and off-center loaded dipole (and many more useful thigs).

I have no idea what a cood is. I have been specializing in aviation electronics for forty years, with a small minor in aviation antennas in concealed locations. I could give a rat's hiney what your monitor receiver tunes. The aviation com band, where ATC transmits, is 118-137 MHz..

I have a website for the antenna I have developed for AO-40. This is NOT a BBQ grill dish, this is the real thing! Watertight HELICAL feed, NO aperture blockage,2' dish is 20.5 dBi gain, 3' dish is 25 dBi gain. 2" crossboom mount.A true performer. Signals from AO-40 at unbelievable squint angles. You should hear what you have missed! I have also posted tips you may find interesting. AMSAT has expressed intrest in my antenna to be sold at Dayton, but I have a limited supply. Drop by my site and just tell me what you think if you like.

Hi!

For better reception of a trunking-system on 468 MHz I'm looking for a beam/yagi which is especially tuned for this frequency.

WIMO in Germany has lots of beams and in their catalogue you can see some machines which are computer-controlled and can make antennas for any possible frequency, but now they don't seem to be able (or don't want) to make such an antenna for 468 MHz.

Does anybody know other firms that are able to make this???

73, Peter Hunt PE1RFR.

Well, maybe he wants to make sure his house isn't moving around.

OTOH, maybe he's really wanting the NDBs way down there in the noisy
bands, so he can practice code :)

Jim Weir wrote:
"Then you really should not answer questions regarding antennas. You are clueless."

I`m in good company. Jim`s response above was to my statement:
"My experience with receiving antennas is good when they are slightly too long."

I suggested a vertical antenna, with an ungrounded element of 1/4-wavelength at about 108 MHz for use at higher frequencies.

A 5/8-wavelength vertical antennsa is used by some broadcasters to get more signal strength perpendicular to the antenna along the horizontal and thus increase their primary service area.

Remember that in antennas reciprocity rules. That is, a good transmitting antenna makes a good receiving antenna for a given wavelength.

A 5/8-wavelength antenna is 2.5X the length of a 1/4-wavelength antenna. 108MHzX2.5=270MHz

As frequency increases above 1/4-wave resonance of 108 MHz, the vertical antenna performs better toward the horizon at least up to 270 MHz in its directional response.

Many 5/8-wave mobile antennas are sold to replace 1/4-wave VHF/UHF antennas and exploit this drectional gain of the longer antenna. I assumed that the loss in gain at higher elevation angles would be compensated by the usual case of an aircraft`s proximity when its elevation angle is high with respect to the receiving antenna`s position. When the aircraft is near, its signal may be stronger.

As I said in my previous posting, matching the transission line is not such a serious requirement for a receiving anenna as for a transmitting antenna. Mismatch causes increased loss. Mismatch may upset your transmitter but it won`t shut down your receiver. The additional mismatch loss also is imposed on external noise on and around the received signal so that deterioration of the signal to noise ratio is not severe.

There you have my reasons for saying:
"My experience with receiving antennas is good when they are slightly too long."

What's inherently wrong with Richard's statement? SWR and antenna efficiency are not as significant in the receive mode as they are in the transmit mode. In receive mode, the most important issue is whether or not the intended receive signal is above the ambient noise level. The second issue to be concerned about is the receiver sensitivity and receiver noise. Many short receive antennas work just fine with low efficiency and high SWR. The AM antenna on your car being a good example.

3093. Cell Tower Effects Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-13 16:48:30 UTC
From: Richard Myers <rkmyers@mediaone.net>
Message-ID: <yNwa8.819$TU4.523958@typhoon.ne.ipsvc.net>
Source record: 148538

Hi All,

The local cell provider has just proposed putting a 150' cell tower behind my house. This would put the tower base at about 75 yards from my house. What are the MPE limits for cell frequencies? I know that at Microwave frequencies possible damage to eyesight is possible if MPE limits are exceeded, so I am hoping the cell provider is as concerned about RF safety as I am. I have been very careful with my own station to safeguard the health of my family and neighbors by staying well below the MPE guidelines.

Also, I operate primarily on HF using a multiband vertical and G5RV. What are the chances that a cell tower that close to my station will cause harmful interference?

Thanks for any insights.

There are no dumb questions, Bob, but this ng seems replete with dumb answers.

Yes, a receive antenna can have a SWR. It is identical to the SWR you would measure if you hooked a transmitter to the antenna and measured it that way -- the guts of the reciprocity theorem.

If you care to think of it this way, you certainly may...you measure the VSWR by the transmitter method in volts and by the receive method in microvolts. Just because you change six orders of magnitude in the voltage doesn't make the RATIO (vswR) any different.

Hi Bob:

The SWR is simply an indication of much the antenna feedpoint impedance
differs from the characteristic impedance of the transmission line.
Transmit or receive mode does not matter for the antenna SWR relative to the
feedline impedance.

Steve

How do you differentiate "measuring" SWR by the transmitter method versus the receive method? How is the receive method set up different than the transmitter method set up? When you use millivolts rather than volts or microvolts, what method is that?

Steve

Jim Weir wrote:

"Make up your mind!"

This was Jim`s response to "reciprocity rules".
"That is, a good transmitting antenna means a good receiving antenna."

All true. No contradiction.

Jim also repeated my statement:
"As I said in my previous posting, matching the transmission line is not such a serious requirement for a receiving antenna as for a transmitting antenna. Mismatch causes increased loss."

All true. No contradiction.

The antenna is the same. How this affects transmission and reception depends on the transmitter and the receiver.

The antenna has the same gain, radiation pattern, antenna drivepoint impedance, efficiency, if transmitting or receiving.

Jim did not repeat what I said about the difference these characteristics make on the process of reception and transmission.

I remember saying a mismatched transmitting antenna might shut-down your transmitter, but the same antenna weouldn`t shut-down your receiver. I remember saying that the loss produced by the mismatched antenna might limit the reach of your transmitter, but wasn`t as bad for your receiver because some of the external noise a receiver sifts through for a signal is rejected and dissipated right along with the desired signal. Thus, the signal to noise ratio isn`t hurt as much as the signal is attenuated.

All true. It isn`t the antenna which changes, it is the device using the antenna. A transmitter is different from a receiver in exactly what it needs from an antenna for satisfactory operation. An extreme example to make the point:
The receiving antenna needs to be located in an area quite free of electrical noise for satisfactory operation. The transmitting antenna needs to be located in an area free of live explosive detonators. It could be the same antenna.

Thank you for your support Steve Best!

Source record: 148539

Unfortunately, this answer isn't correct. Bob is right -- an antenna
can't have an SWR, only a transmission line can have an SWR. As Reg
often points out, we have "SWR" meters that we can connect to an antenna
and get a reading. But the reading doesn't really indicate anything
about standing waves. What it's really measuring is the antenna's
impedance, then mathematically converting that into the SWR a 50 ohm
transmission line would have if that impedance were to be connected to
the line as a load.

The antenna impedance is the same when transmitting and receiving, per
the reciprocity theorem.

The feedline between the rig and the antenna does have an SWR, and its
value will be different when transmitting and receiving, unless the
receiver and antenna both have the same impedance or reflection
coefficient. This is because the SWR is determined solely by the
impedance of the load seen by the transmission line and not by the
source impedance. For example, suppose the input impedance to the
receiver is 50 + j0 ohms, the antenna impedance is 25 + j0 ohms, and the
line characteristic impedance is 50 ohms. When transmitting, the line
SWR is 2:1, because the load it sees is 25 + j0. When receiving it's
1:1, because the load it sees is 50 + j0.

Yes, that is so. My simplification error. I didn't see the question as
that technically specific, but more of a general "howzit work" question.

Yes, that is also so, from the receiver/transmitter's point of view. But
now we have a generator called an antenna that is creating an EMF in a 25
ohm system and trying to drive a 50 ohm system. To the ANTENNA and to the
universe as a whole, we still have a 2:1 mismatch between antenna and
transmission line. The mathematics is the same. In this case, if you were
trying to measure the VSWR of the system from the antenna's point of view,
you would need a VSWR meter calibrated for use in a 25 ohm system.

That's silly. A friend who lost his ability to drive (and his license)
to a stroke bought a new car for others to haul him around in. I bought
my first HF rig and 2-meter rig in anticipation of becoming licensed
because I was due to move to an area with few dealers but high prices.
Neither is illegal; nor do I see any morality in refusing either sale.
YMMV.

Gentlemen:
When using an antenna for receiving remember that in order to get as
much of the intercepted radio wave energy as possible to the rf amp
stage of a receiver you must have the most efficient antenna as
possible.
This means that if you have a good match for transmitting you will have
a good match for receiving. A low SWR and an efficient transmission
line are required to achieve this situation.

Standing waves are created whenever you have an alternating current
flowing in a wire. The radio waves intercepted by an antenna generate
these alternating currents. Thus in a tuned antenna standing waves of
1:1 are present.

3111. Helical Antenna Sidelobes - Pls Help

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-13 21:04:53 UTC
From: Gollywog <_eng@ilos.net>
Message-ID: <VxAa8.842$8i2.26274@news2.mts.net>
Source record: 148549
Cross-posted to: rec.radio.amateur.antenna,sci.electronics.design

Hi all,

I've found what appears to be a cheap and easy homebrew helical suitable for use in a current project. If possible I'd like to reduce the side lobes that appear in the horizontal plane radiation pattern. Anybody here doing Phase 3D (AO 40) satellite stuff, etc could give me some pointers? What if I just bent a 1 foot wide piece of aluminum to make a 320 degree (or so) cylindrical shield. The antenna indicated would then be mounted inside and be pointed out the vertical slit. Would this "shear off" the side lobes?

2.4GHz Homebrew Helical by Jason Hecker is at :

http://users.bigpond.net.au/jhecker/

This is a single page site. The radiation patterns mentioned above appear at the very bottom of the page.

Thanks,

Mike Whitfield (VA4MGW)

==========
I can't stand it any longer !

Yes, antennas DO have standing waves on them. There's a beautiful standing wave on a half wave dipole. And an even better one on an unterminated Beverage. They even have Zo's.

But here we are concerned with SWRs on feedlines. But it has nothing to do with the 'reciprocity' theorem.

There is an SWR on the line between the antenna and radio receiver. The signal generator is the receiving antenna. The testing signal is the received signal. Or just antenna noise. The load is the receiver input impedance.

Reflections occur due to the receiver input impedance not matching the line impedance.

And so the receive SWR on the line can be, and very often is, quite different from the transmit SWR on the same line.

Peculiarly enough, in a practical situation, the SWR on receive is usually considerably better than on transmit. No prizes for explaining why this should be so.

Hi all:

After reading this thread for awhile, I went to the ARRL web site, and did a search on "eqsl", "e-qsl" etc. and I found a few mentions of e-qsl, but nothing that mentions that the ARRL is doing anything but thinking about accepting e-qsl's. So is this really true or is someone reading more into ARRL thinking about it than has happened yet.

3115. Re: eQSL's NOW ACCEPTED by ARRL for DXCC

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-13 22:05:26 UTC
From: Charles Johnston <ctj92@cableone.net>
Message-ID: <3c6ae327@news.bnb-lp.com>
Source record: 148553
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.policy

Hello John,
The real-low-down-skinny is that eQSL confirmations are now accepted
at the ARRL - DXCC desk provided the eQSL web site "mail-a-card" service
is used. Basically this way eQSL becomes a sort of qsl manager by
verifying logs from both parties of a qso and then mailing out the card.
This has never before been done and thus it is a '" news-item " for
all DXers that prefer the economy, speed, ease, and fun of electronic
qsl'ing. Statements to this affect are plastered all over the eQSL
website including a copy of the email from Bill Moore at the DXCCC desk
verifying that eQSL cards handled in this manner would be valid for
DXCC.
It can be seen by some that this is a new approval, and a change in
policy, by the ARRL since no electronic qsl cards of any type have ever
been "accepted" before for anyone under any conditions. But..also
since the ARRL is only accepting eQSL cards that have been mailed others
can say there is no ARRL policy change as they are "still accepting"
mailed cards. It can go either way.... Personally since nothing like
this (electronically derived qsl cards) has ever been "approved" for
DXCC before I see it as a "change in policy" by the ARRL.
Others disagree....be that as it may there is no argument that this is
a real shot-in-the-arm for eQSL users and will very likely spin-off as
more participation in the DXCC awards program to the benefit of the ARRL
since only it's members are eligible for their own brand of awards. I
see it as a win-win situation.....and..it most definitely is "something
new" IMHO....

Dave, WD9BDZ wrote:
"Standing waves are created whenever you have an alternating current flowing in a wire."

Nothing is prerfect, so there is always some reflection at the end of the line. But for practical purposes, standing waves are not always created when you have a-c in a wire. It takes a bounce at the end of the line (or somewhere along the line) to cause some of the energy to reverse direction. This reflection results from an impedance bump caused by some degree of mismatch. It is the interference patterns caused by the combination of the incident and reflected (forward and backward) waves that produce the ratio of maximum to minimum voltage or current on a line that we call SWR.

Dave also wrote:
"The radio waves intercepted by an antenna generate these alternating currents."

Fair enough. If the feedline doesn`t present a matched load to the antenna at its feedpoint, the feedpoint rejects some of the energy available in the antenna. This energy reverses direction because it has been rejected. It is reflected. It reverses its direction of flow in the antenna and is re-radiated.

Dave also wrote:
"Thus in a tuned antenna standing waves of 1:1 are present."

A tuned antenna is terminated in an open or short circuit. This invariably causes reflection and SWR on the antenna itself.

A traveling wave antenna, on the other hand, is terminated in its characteristic resistance, has no reflection, and the SWR on the antenna is very nearly 1:1.

Best regards, Richard Harrison, KB5WZI

Chalk-up another acceptance for eQSL's......

Confirmation was received today from the president-elect of the
3905 Century Club that their awards program will accept hard copies
of eQSL's as confirmation. The hard copy can be printed by the
recipient on his home computer if desired, or you can use eQSL's service
to have them printed and mailed to you.

Either is OK for Century Club awards.

The folks at eQSL solved two problems. Firstly they found a way to make their record keeping system of some value to some people. Without the document being submitable for credit, few people wanted them. They're too easy to counterfeit on the computer. Secondly, they found a way to make some money. By charging a dollar and then sending the card out at the postal card rate of 22? cents, finally they are in the black. Amateurs have been creating and mailing out electronically created cards for years. There is nothing new at all there except the process perhaps of 'ordering' the card on-line.

Hi folks. I've got a D104 that's not perfect looking by any stretch,
but it seems to work fine. It's missing the sliding PTT lock ring ,
has a couple of holes in the base, and the base has been repainted
badly. No connector on the wire. The head actually looks decent, no
visible damage.

You get the picture.

The good news is that it's yours for $15, you ship.

It's easy enough to receive signals from enroute aircraft, but picking up low-power ground signals over a point-to-point path can pose a hefty challenge--especially if there are lumps in the way (sub-microvolt vs. millvolts). I use a 8-element wideband yagi with a GaAsFET preamp strapped to the boom to get that job done around here. At minimum, I'd recommend an outside omni-directional antenna with a low-loss feedline, or better yet, a small yagi pointed dead-on at the airport. With a decent antenna, you'll hear not only the tower, but also traffic on the ground. Anything less, and you're likely to miss a good portion of the show.

Good luck with your installation. With a possible grumpy exception or two, most pilots roaming the freindly skies are more than glad to help anyone who likes airplanes!

Source record: 148560

Standing wave ratio is defined as the ratio of the maximum voltage along a line to the minimum voltage which occurs at another place along the line. The distance along any line between maximum and minimum volts is always 1/4-wavelength.

Take a 1/4-wave vertical. Although it has only one conductor undoubtedly it is a transmission line. A typical value of Zo is 400 ohms. Its bottom-end input resistance measured against ground is the well known figure of 37 ohms.

Because it is 1/4-wavelengths long it behaves, just like any other line, as a 1/4-wave transmission line transformer. And so the 37 ohms is transformed, looking into the top end, to a resistance of 400*400 / 37 = 4324 ohms. (See ARRL books on 1/4-wave line transformers if you don't believe me).

Now feed 100 watts into the bottom end.

The voltage at the bottom end will be Sqrt(100*37) = 60.8 volts.

Now feed the same 100 watts into the top end with the bottom end grounded.

So the voltage applied to the top will be Sqrt(100*4324) = 657 volts.

The antenna is quite indifferent to where it is fed. It will radiate 100 watts regardless.

Let's look at the ratio of the two voltages, max and min, at top and bottom which are spaced apart by 1/4-wave of transmission line.

SWR on the antenna = 657 / 60.8 = 10.8

Incidentally, considering the antenna as a tuned circuit, it turns out that SWR is also equal to the resonant Q. And so the operating bandwidth is MHz / SWR = MHz / Q.

There are other ways of arriving at the same conclusions.

Fascinating, isn't it ? And all so simple.

If anybody should complain about about how to apply 657 volts to the top then apply 152 milliamps from a constant current generator. It's easier on the brain cells !

In regard to the reflection, does it matter whether it is originating from the transmitter, as in a transmitting antenna, or whether it is originating from the antenna, as in a receiving antenna? Same swr, either way?

==========

I could have added that by far the easiest way of applying 657 volts to the top of the 1/4-wave vertical would be to apply 60.8 volts to the bottom end and let the resonant rise in voltage due to Q = 10.8 do everything all by its lonesome self.

But that would have been TOO simple. ;o)

Why am I reminded of Stanley and Oliver and a lonesome pine ?

Source record: 148567

god my head hurts.....

here's a couple of ideas.....

1) get a pair of rabbit ears, hook them to the receiver and adjust for
best reception (including length)
2) failing that, if you have trees around the property that are visible
over the roof line (might not even have to worry about it) then get a 20
to 22" scanner antenna or just a whip antenna of the same length, paint
it a light gray with flat paint, go up on the roof pretending to clean
the chimney and mount it on the cap and drop the coax down the pipe.
3) try winding a few turns of wire around either the cable or phone
lines entering you place and see what you can get.
4) see if the rain gutter or down spout are metal and attach a wire.
5) try attaching a wire to the chimney pipe
6) dangle some #22 or #24 wire out the top floor window or throw it on
the roof, along a fence, cloths line etc.
7) get a VHF preamp
8) copper wire in a loop or dipole stuck to a window, you can even use
copper tape for alarms if you like.

Frankly when it comes to receiver antenna I wouldn't get too worried
about it. If your going to transmit then it's another story. The KISS
rule applies in most cases. Keep your feed wire as short as possible,
and a tuner will help out for the HF range down the road. There's got to
be hundreds of receiver antenna plans on the net including tunable ones
you can try.

Hi :

But my point is I see nothing from the ARRL that this is true.

so what gives?

>about standing waves.

Hi Roy,

Almost every common example of antenna discussed on this board is of
the class called Standing Wave as opposed to Traveling Wave antenna.
The distinction between antenna and transmission line is only one of
application, there is no engineering demarcation where the Physics
shifts to follow the intended use; the difference of operation lies in
the change of boundary conditions - still employing the same math to
solve either situation. Further, because every common example of
antenna is a NON-LINEAR example of transmission line, appeals to
constant SWR and other characteristics confined to simple transmission
lines does not faithfully translate in discussion.

And as for that Old Wife's mumbled tale about the impossibility of SWR
meter operation is simply nonsense. A manufactured argument for the
sake of argument whose wheezing through pointless postings adds
nothing to the discussion. I find it tiring to read this creationist
quality academic argument where punchinello demonstrates no particular
skill, much less care, with the techniques of this measurement beyond
the incessant denial. His tainted argument goes to include how
useless certain instruments are because they do not reveal phase (as
if it were the be-all of our concern).

This last Old Wife's tap dance reveals a prostituted faith in
instrumentation only to condemn it. This is called the straw man
argument and is invested with cynicism rather than education.

The measure of SWR has always been one of technique - there are many.
I have measured the actual standing waves in situ, I have measured
them by inference, I have measured them by altering the system. The
differences of measure are strictly one of economy or practicality.
Rarely do the measures differ, and only as a product of the added
reflections offered by the measurement (direct measure of the actual
standing waves also shifts them and thus introducing error).

Having flattened innumerable standing waves (through yet other
techniques such as double stub tuners), I find there is no particular

magic involved (more a matter of skill), nor is there any requirement of faith outside of common sense. I can well imagine a first year music student with a valved horn (or flute for that matter) could cope easily with the discussion of the mechanics.

That doesn't sound right. With a receiving antenna, the antenna is the source
and the receiver is the load. The SWR depends on the load inside the receiver
which is probably not the same value as the antenna load during transmitting.

How about making your own - it is very easy to do, and will likely be a lot cheaper and give you much more satisfaction. I have made several yagis (between 10-20 elements) for 477MHz (Australian UHF CB) that have worked as well as if not better than commercial made antennas. There are heaps of sites and software packages around that will make it easy to do - I haven't made one for about ten years now, but it was quite easy to do when I was playing around with them. OK the first couple needed some major reworking, but after a while, I had it sorted out, and made some pretty decent quality antennas that are still working today.

Well, I have to admit it has an RFI problem on 10m. The diodes are
rectifying the RF and activating the circuit. Here's my latest
thought which I will try tomorrow. One relay, that's all.

```
Wires to the screwdriver motor
----------------+----------------------------------------> Motor
----------------|--------+--------------------------------->
| 12v |
+-Relay--+

GND------||---------+---TSTR
NO |
+---TKEY
```

I didn't miss the point. You said "kid" in your original post, now
you're changing it to "anyone". Frankly, I don't care who you sell
stuff to, I just think it's silly to miss a sale because someone doesn't
have a license to use whatever it is.

My next door neighbor is an auto mechanic who traded some repair work
for a two meter rig. Since he has no license and plans to sell or trade
it away, has he committed some kind of transgression?

No need to reply. This thread has become a big yawn already.

Hello John,
Did you visit the eQSL web site and read the email from Bill Moore of the DXCC Desk? I cannot speak for why the ARRL webmaster does or does not place what many believe to be important "news" on that site. You might consider emailing them. I would like to see their reply posted here.

My personal opinion is that they are reluctant to possibly steer anyone over to eQSL services since they (the ARRL) are going to launch the Electronic Logbook of the World ....one of these days.
It will supposedly provide for a 100% all-electronic qsl confirmation system that would feed directly into their own awards programs that would not require any paper-based qsl cards at all. However it looks like eQSL has done the end-around now by obtaining the "go-ahead" from Bill Moore himself that basically "allows" electronic eQSL's to be "accepted" for DXCC awards.

The eQSL system has many advantages over the yet-to-be-released Logbook of the World. With the LBOTW, once released and in operation, past qso's are not accepted. Not so with eQSL Furthermore....there will need to be digital signatures acquired and approved , as well as new additional ARRL fees (according to ARRL), and special ARRL- LBOTW software will need to be purchased or existing logging software will need to be upgraded (at a cost) to interface with the LBOTW system. There will need to spend $$$ spent and numerous hoops jumped through just to get only your recent qso's accredited. And of course don't forget you'll need to pay ARRL dues too....

None of this nonsense is required with eQSL.....they really have a better way and it shows already with the upsurge of acceptance (or call it usability) by various Ham Radio awards organizations. I don't chase awards anymore except for my own satisfaction and for ego-motivated "bragging rights" but I have to say I really get a kick out of the easy and automated way eQSL allows me to provide confirmations for any station I qso with...and now they are DXCC accepted too.....where is the down-side? I don't see it......

Hi there Jimbo....
I wondered where you had gone....well as usual you are not looking at the silver-lining Jim. The eQSL "mail-a-card" service (which has recently been OK'd for DXCC) still puts $$$ in the mailman's pocket when eQSL sends out the cards through (that's right) the USPS.

And so now your point would be what exactly?

I'm going to break it you easy as I can sunshine......eQSL is getting stronger, more widely accepted, certainly more widely used every day. Moreover eQSL is saving Ham's $$$, time, frustration, and $$$ pilfering by unethical foreign postal workers - and - no-good DX op's that collect $$$ for 1000's of cards but send out only a couple dozen confirmations a year....just enough to keep the "believers" sending in that money....you know that Jim.....

Now..is that the way you prefer?
Thanks for posting....

Obviously, all receivers should have 10dB attenuators fitted as standard equipment. One can't be too careful when it comes to SWR... ;-)

Hello Jim,
Man...you really don't know what the hell you're talking about (on most topics) but especially on eQSL. What would prevent p50dx@yahoo.com from "uploading his logs" and then having eQSL start "passing them out for a buck a piece" is the eQSL Authenticity Guarantee mechanism at eQSL. It requires a scanned image of the Ham's license be submitted beforehand.

Now before you start with how any system can be "tricked" or cards and licenses could be "faked" also recognize that most honest-hearted Ham's have no interest in ill-gotten "awards". Honesty and integrity cannot be legislated or enforced on anyone. Doing the right thing will always be optional.

Furthermore the odds of a convincing license forgery are miniscule at best. Most government authorities have selected a paper stock that would be very difficult to duplicate by amateurs. Take a look at - your - ticket Jim....are you going to be able to duplicate that exactly?

Still nothing is perfect.....I am sure that literally thousands of bogus and forged "real qsl cards" have been used for awards for a long time. In addition it is just a hobby award Jim....we are not dealing with the CIA or the Ft. Knox Federal Reserve.

Lastly if a few butt-holes do manage some way to "cheat" they are only cheating themselves. It would take nothing at all away from any awards you are I or anyone else legitimately obtained.

Maybe see you on-the-bands one of these days....

Just how much power do you intend to run? If the center of the dipole is 75 ohms, and you feed a full kilowatt to it, the voltage across the insulator will be a gigantic 273 volts, just measurably higher than the 240 volts difference between the red and black wires in your electric power connection. Of course, if you are lucky enough to have one of those 100 kW Collins 308U modules I have been looking for, then use a big insulator.

Bob, K5QWG wrote:
"In regard to the reflection, does it matter whether it is originating from the transmitter, as in a transmitting antenna, or whether it is originating from the antenna, as in a receiving antenna? Same swr, either way?"

Yes, it can make a difference which SWR is being considered. There can be two different SWRs. It is not necessarily the same SWR in either direction of transmission because the loads can be different at opposite ends of the transmission line.

In a transmit situation, the transmitter is the energy source, but the reflection is caused by reflection from an antenna which is not matched to the transmission line.

The transmission line, if it is long enough to allow significant phase shift, compels energy traveling the line to conform to a voltage to current ratio called the "characteristic impedance" of the line.

If the line`s load impedance is too low (less than the characteristc impdance of the line), the line can`t supply enough current to the load at the available line voltage. There is too little current traveling in the wave and the voltage across the load is low.

If the line`s load impedance is too high, the line isn`t supplying enough voltage to put all the current traveling the line into the high load resistance and the current through the load is low.

It`s the maximum power transfer thing. Without a match at the load there is reflected power to produce SWR.

In a receiving situation, the antenna is the energy source. It has a radiation resistance. In the case of an antenna fed at its maximum current point, the radiation resistance and feedpoint resistance are the same.

The resonant antenna with a maximum current feedpoint can be represented by a Thevenin equivalent circuit. It consists of a voltage source equal to the received voltage in series with the radiation resistance of the antenna.

If the feedline connected to the antenna presents an impedance to the antenna equal to the radiation resistance, maximum power transfer occurs. That means 1/2 the antenna power is delivered to the transmission line and 1/2 the antenna power is consumed by the radiation resistance (It is re-radiated).

Until the energy transferred from the receiving antenna reaches the receiver there is no chance to establish an SWR. The apparent SWR is 1:1. If the energy traveling to the load encounters a match at the end of its journey, there is no reflection, and the SWR continues to be 1:1. If there is a mismatch at the receiver, there will be a reflection and an SWR greater than 1:1.

It is always the match at the far end of the transmission line which determines the SWR.

Best regards, Richard Harrison, KB5WZI

3144. NMO mounts, what's the difference?!

Hello all. I am having a problem. I recently bought a dualband antenna that was listed as requring a 'Motorola NMO style' mount. I bought a Larsen 'NMO-MM' mag mount, listed on their website as a 'Motorola style mag mount'. The antenna and the mag mount are not compatable. The antenna requires that the mount have a female recepticle to screw into. The mag mount that I received has a sort of nipple like bump in the middle of the part that the antenna screws into, making the two non-comptable. Does anyone have any idea what type of mount I am supposed to use for the antenna I bought?

In the mean time I have bought a Hustler dualband NMO mount whip/coil, which I plan on putting in place of my 2m Hustler - just unscrew the 2m from the Hustler magmount base and screw on the dualband version of it, but I'd still like to get the proper mount for the other antenna I bought.

Source record: 148685

What's really important is understanding what's going on. I've found a great deal of misunderstanding about SWR, impedance, and transmission lines everywhere I go -- in technical talks I give, in questions I'm asked by EZNEC users, and in this newsgroup. Certainly there are standing waves on an antenna (except traveling wave antennas). But calculating a "standing wave ratio" is meaningless. Pick a Yagi, log periodic, or phased vertical array of your choice, and tell me what its "SWR" is, what it means, and what it's good for. Telling people that antennas have an SWR is, I feel, misleading and a cause of confusion.

And surely, Richard, with your exemplary education in the fine arts, you don't have to stoop to plagarizing Reg's "Old Wives" tale (singular or plural) invective as the best way to make a point. That's something you should only need to use when you can't produce any rational evidence that someone else's point of view is incorrect.

From an electromagnetic field standpoint there's no difference but boundary conditions that divide a transmission line, antenna, the ether (or aether if you prefer), and the circuit at the other end of the line. Yet as an engineer I find it very convenient to establish boundaries between the various components and apply different analysis techniques to each. (And I'm not alone in this.) Although all these analyses have Maxwell's equations at their roots, each is simplified in a different way to make the problem easier to solve and, to my mind, easier to understand.

I'd appreciate a single reference in any textbook or professional paper in which the SWR of an antenna is calculated and used for anything meaningful.

Vacation?

Get real Walt, take the up and coming Mellish Reef DXpedition (which I am involved in) for instance.

Do you honestly think a rough 3 day sail each way (real puke material) then 10 days of flat out operating to try and work as many "deserving" as possible under extremely harsh conditions, battling tick infestation and sleep depravation because of the incredible bird noise is a vacation???

...while you operate in the comfort of your shack.

I just had to stop a couple days ago and grab the two nice black cases at one dumpster; they turned out to be a partly stripped 386 (burned up BIOS chip, a few usable components and a pretty case) and a mostly stripped (MB CPU FDD and an old vid card still in there) K6/233. (no power supply, though, or it'd be my Linux box already) Also grabbed a practically new vaccuum cleaner that only needs a belt, and a BJC-250 printer minus the power supply.

I like it when people move and decide they don't want to carry the bulky stuff, since around here, they just set the still-good-but-unwanted stuff beside the dumpster so anybody who wants it can rescue it easily. Still waiting for a broken VCR or two, though, and I've been meaning to ask the Salvation Army store if I can dive their dumpsters. (I don't actually check inside the residential ones; just get useful stuff that's sitting beside them, but SA's probably don't have nearly as many dirty diapers and rotten TV dinners in them, but they probably toss a fair amount of stuff that could flesh out my junkbox quite nicely.)

As usual the skeptics are out in force.. but they'll come around oneday--
10.3 million qsl on line can't me Eqsl is doing poorly.. they don't require
any donation if you don't want to give one.. so it's not a money earning
scheme like some on here have suggested.. I for one think it is a breath of
freash are in Qsl my Qsl ratio to qsos with dx stations has gone up 100
percent using eqsl. And I don't have to wait two or maybe three years for
the buro! Also if you don't for whatever reason want to join the Arrl , try
sending your cards via their outgoing Buro..

The Time for Eqsl has arrive. and it's working very well. Trust in the
future more and more award committees see it as a viable way to exchange
confirmations for awards.

Just my two cents worth now will get off my soap box..

(I'm in no way conected with eqsl other than a happy user of their system.)

What on earth is the 3905 Century Club?

As it only has a 'president-elect', maybe it doesn't even exist yet!
Or maybe it has been set up by 'e-qsl' themselves? Allegedly.

>

Hi Roy,

You are correct in stating that the actual standing wave (re: antenna SWR) exists in the transmission line itself. It is common practice to define antenna SWR or characterize an antenna in terms of its SWR with respect to some common feedline characteristic impedance. In doing so, it is clearly understood that the standing wave to which we refer exists in the feedline. The meaning of antenna SWR is also clearly understood in that it provides an indication of how closely the antenna's feedpoint impedance matches the characteristic impedance of the feedline to which it is connected.

Specifically discussing antenna SWR, it is also understood that antenna SWR (its mismatch with respect to the feedline impedance) does not change from a transmit mode to a receive mode. As you correctly state, the SWR on the feedline may differ between transmit and receive mode depending on the differ in antenna impedance and receiver impedance.

Steve

3905 Century Club is an United States based net with session on 160, 80 and 40 meters SSB, 80 and 40 meter CW and several digital modes on 80, 40 and 20 meters. They offer awards to participants and, more importantly to this discussion, is a 25 year old organization. The FCC thinks they are for real as several 1x1 special event calls have been issued to them in honor (honour) of this anniversary. The president elect happens to be a ethical ham.

I'm not sure why you think it necessary to cast aspersions on this organization. (No, I am not a member; yes, I have participated in their nets on occasion).

Yes, but not all of us have, or even want new technology. For example,
our Navy has had radar/computer systems capable of automatically landing
planes on pitching decks for more than 20 years, but the FAA still has
to shut down airports for fog. It follows that DOD's Joint Warfare folks
will have the "jitters" decades before local emergency management and
police and even then some hams will still be sending Morse ;o).

Greetings.....!

I have an early version of the Cushcraft R7. After many years of waving in the breeze (un guyed)(in Nebraska), the base insulator gave up the ghost and broke, causing the antenna which is mounted on a ten foot mast tied to my back fence, to become a "sloper"....(8-<....

I contacted Cushcraft via the website and received a prompt reply that this antenna is no longer supported (I wonder if they realized the pun?) and there are no spare parts available.

Anyone have experience with replacing the base insulator on one of these antennas? Some of the top of the antenna is also bent up pretty well, but I have not been able to get to the antenna to check closely becaue of snow and mud and I'm a wuss....

Any help appreciated...thanks es

They're working on something called "Logbook of the World". I've not seen
any details yet. It looks like a similar plan to eQSL's, but different.
You might find it mentioned as "LOTW" on search engines.

N4DAV wrote:
"Can anybody draw a picture or otherwise help?"

Doing a search on "combiner" or "circulator" would likely give 1000s of responses, but the questioner wants instruction on how to configure multiple repeater T/Rs to compatibly share a single antenna. He`s heard of "isolators, cavities, etc, but don`t know exactly how."

The title of an available how-to book containing a reliable detailed example of what he`s asked for might be helpful.

My last job was as an RF engineer for a major cell phone company (on
800 MHz).

One of the last things I did before I left for greener pastures was to
do a survey of all of their roof top sites. This included taking
pictures and measuring RF levels. This was back when the FCC/EPA were
cracking down on exposure levels.

What I found was that 1) the cell site would have to be running over
100 watts, which is rare nowdays, and 2) you would have to be
physically touching the antenna. I was more worried about the FM
broadcast station co-located with one of our sites in Cleveland---you
had to climb up a ladder within 2 feet of the FM antenna to get to
ours, and they were running a couple of kW. FM broadcast is in the
region where human beings are close to resonant wavelengths.

A microwave link would be of more concern, but again you would have to
be a few feet directly in front of the thing.

You missed your opportunity, Rick. I remember reading about one ham
who got a deal for the cell phone company to build him a new tower,
with new ham antennas, if they could put their antennas on it!

By the way, is the cell tower going to be a monopole or a lattice
tower? If a monopole, chances are there will be nothing else sharing
it. Most sharing I've seen has been on lattice towers.

3167. Re: Two repeaters on one antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-14 14:21:55 UTC
From: richardharrison@webtv.net
Message-ID: <22014-3C6BC803-23@storefull-116.iap.bryant.webtv.net>
Source record: 148705

Adam Cately werote:
"What`s wrong with using a combiner?

For grins, I tried a search on "circulator". There were responses on dance groups, medical devices, and No. 5__: Di Tom Microwave!

Di Tom___"Extensive experience in designing and manufacturing Ferrite Isolators and Circulators since 1987. A standard line of Isolators and Circulators is offered in the selected frequency range from 100 MHz to 40.0 GHz to satisfy specific system requirements."

Love that precision! 40.0 GHz.

All N4DAV needs to do is contact Di Tom with his requirements for a quote.

Best regards, Richard Harrison, KB5WZI

3168. Dual band single coax 2m/70cm base antenna design

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-14 15:18:27 UTC
From: "R. Scott" <kf7qz@yahoo.com>
Message-ID: <3C6BD543.DE2CC4E0@yahoo.com>
Source record: 148707

Not quite sure if the Copper Cactus J would work (Besides I dont like copper cactus looks). IS there a small beam design that is a single coax feed dual band 3 or 4 elem. I cant find my antenna hand book anywhere (Weve been doing a lot of moving stuff around lately) and I just did a net search off of AC6V's site and cannot seem to find one. The commercial ones are "Expensive" as all get out.

Ideas ?

Thanks in advance

3169. Coil Form Material for Screwdriver - Whats best

Besides PVC. Ive seen phonelic (SP) on some designes and plastic on some others. Friend of mine is going to cut the coil form for me and he thinks PVC wouldnt be a good choice so he is requesting somthing more rigid.

Ideas.

Thanks in advance

Rick KF7QZ

Jim, N8EE wrote:
"A microwave link would be of more concern, but again you would have to be a few feet directly in front of the thing."

I built a microwave system between Texas and New York. Hit a snag when one determined Ohio woman wasn`t going to have a repeater in her neighborhood. The FCC, her senators, and congressman, all contacted me demanding r-f exposure data. This was almost 20 years ago. Of course, I supplied the data.

Agitators were confusing ionizing radiation with non-ionizing radiation, and filling gullible heads with nonsense. Some people thought the r-f exposure might make them glow in the dark. The public doesn`t understand that they are not in the microwave beam except at a distance so far removed that the strength is of no consequence. They are terrorized with misinformation.

Oh, we prevailed with the repeater in the Ohio woman`s neighborhood. I hope she`s happy and healthy. The microwave works well.

Best regards, Richard Harrison, KB5WZI

3171. RFI from AC line

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-14 15:42:37 UTC
From: Stan Huntting <ng@huntting.com>
Message-ID: <NVQa8.7096$qt6.626299@newsread2.prod.itd.earthlink.net>
Source record: 148708
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.misc

I'm building a new home and trying very hard to make it a low RFI environment. I'm high in the mountains with few neighbors. I'm the electrician.

I have dual 200 amp AC services, all the way from the pole: one for "dirty" loads (mostly things with electric motors and other inductive loads) and one for "clean" (the radios) loads. I am filling up the "dirty" load panel faster than the "clean" load panel and I am looking for loads that I might move to the clean load panel.

Two possible candidates are the electric hot water heater (conventional Rheem 50 gallon with dual 4500 watt elements) and the electric range (GE Profile, smoothtop, conventional oven - NO convection). How noisy are these?

Unless you are in a rural setting, the cell phone xmitters are running
a pretty low power to avoid interfering with other, non-adjacent,
cells.

You may, however, experience difficulties when the cell tower takes a
lightning hit. My nephew lives across the street from a 400' radio
tower and he frequently loses his ISDN router when the tower takes a
hit. (Yes, he has a whole-house surge suppressor and point-of-use
surge suppressors.)

Virginia code ï¿½ 15.2-2293.1. Placement of amateur radio antennas.

Any ordinance involving the placement, screening or height of antennas shall reasonably accommodate amateur radio antennas and shall impose the minimum regulation necessary to accomplish the locality's legitimate purpose. In localities having a population density of 120 persons or less per square mile according to the 1990 United States census, no local ordinance shall
(i) restrict amateur radio antenna height to less than 200 feet above ground level as permitted by the Federal Communications Commission or
(ii) restrict the number of support structures. In localities having a population density of more than 120 persons per square mile according to the 1990 United States census, no local ordinance shall (i) restrict amateur radio antenna height to less than 75 feet above ground level or
(ii) restrict the number of support structures. Reasonable and customary engineering practices shall be followed in the erection of amateur radio antennas. This section shall not preclude any locality, by ordinance, from regulating amateur radio antennas with regard to reasonable requirements relating to the use of screening, setback, placement, and health and safety requirements.

Rick,
The problem with PVC isn't it's rigidity, but it's
suceptibility to distortion from heat. If you try to
run more power than your antenna can handle, it's usually
converted to heat which tends to do 'bad' things to PVC.
The hot wire windings melt into the PVC causing the windings
to loosen, maybe start slip/slidding on the coil form and
nothing good comes of that. In real drastic situation, the
coil turns into an inverted "L"...
'Doc
PS - No fair counting spelling.

The only things that are noisy are devices with semiconductor power controls; UPS, SCR controlled light switches and the like. Since most RFI is radiated and picked up by an antenna, your approach is costly but ineffective, unless you bury it all including the primary out to where it is no longer within line of sight of the tallest antenna you plan to install. Just out of curiosity, what, besides your radio do you consider quiet?

Induction motors are one of the quietest loads found as far as RFI is concerned unless it is equipped with an adjustable speed drive (ASD) whereupon it becomes among the noisiest and hardest to cure. The water heater and range are silent, UNLESS they use semiconductor power control. Even universal motors are getting quieter these days, and can be easily quieted with a couple of capacitors on the brushes. What else?

The MPE limit for frequencies of 30 - 1500 MHz is f/1500 mW/cm^2. This is based on the ANSI/IEEE C95.1-1992 standard - General Public Exposure. For AMPS band cellular, this translates into an MPE limit of about 0.6 mW/cm^2. This translates to 6 W/m^2.

To really answer your concerns on power level emissions from the cell site, you need to find out how much power is being transmitted and what the antenna gain is.

The maximum transmit power used in a cell system is about 500 W. However, it is very unlikely that the tower near your house transmits at this power level. The actual transmit power level will vary depending on whether the cell service is in the 824-896 MHz band (AMPS) or the 1850-1990 MHz band (PCS). The transmit power level will also vary depending on whether it is an analog system or a digital system. It will also vary depending on the range they intend to cover.

The antennas used in cell sites may have a gain up to 15+ dBi. At a maximum power of 500 W, a 15 dBi antenna will increase the effective radiated power to about 16 KW. Cell sites would not likely use a maximum gain antenna at maximum transmit power. 16 KW effective radiated power is an extreme unlikely estimate. I think an environmental evaluation is required by the FCC is the ERP exceeds 1 KW.

At your distance of 75 yards, 500 W power into an isotropic antenna with 0 dB gain results in a power density of approximately 8.5 mW/m^2 (AMPS band). With the 15 dBi gain antenna this will increase to about 0.3 W/m^2. Well below the 6 W/m^2 limit.

The other factor to consider is that the main beam of the transmit antenna will be pointing well beyond your house. The signal at your house might be down about 20 dB from that of the main beam. This will reduce the power

density down to about 2.8 mW/m^2. It will decrease from here with lower antenna gain and less total transmit power.

Steve

As others have noted (in fan e-mail), my invective is not the one note
song of Punchinello's invention - hence plagiarism is hardly
applicable.
;-)

At worst it could be called boring through repetition, and in that
manner it is very plagiaristic - if it didn't have some entertainment
value (again, missing from the original).

In fact it is a very common device of irony, so common that, again,
plagiarism is not a factor (and has been upheld as an accepted
practice by the courts).

I may take your comments to mean that I should invent a new attack?
Nothing succeeds like holding up a mirror. As a practiced writer I
choose styles that are consistent (meaning the revelation of clowning
needs to be done with clowning - however this has to be done without
falling into the classic trap of the "fallacy of imitative form"
something no one has challenged me with). The way to bell the cat of
fractal antennas was to overwhelm the ersatz science with real
science. When push came to shove, the arguments of the ersatz science
collapsed in their reflection.

>meaningful.
>
>Roy Lewallen, W7EL
>

Hi Roy,

A single reference? I would say that EVERY reference makes use of the SWR in illustration, so much so that asking amounts to being blind to the forest because of the trees.

Is it meaningful? How is it that it is meaningful on one side of a connector, but not the other? The simple answer is there is more metal mass on one side than the other. That is the difference between a long 20 gauge feed wire(s) compared to short, quarter inch thick fed elements. This is not a technical rebuttal so much as an accident of design.

Appealing to
>antennas have an SWR is, I feel, misleading and a cause of confusion.
is a matter called projection. To faithfully avoid any discussion in anticipation of other's confusion would silence the newsgroups in a microsecond. One such example of confusion is the contradiction of statements that follow from the attempt to dumb down the topic.

Compare earlier
>Bob is right -- an antenna can't have an SWR
with that above
>Certainly there are standing waves on an antenna
now brings into confusion: what is a standing wave?
The simple answer: it is what is was and always has been.

I can understand your hesitancy to discuss the mechanics of the antenna as transmission line, you have complained of this about me in the past. I am not confused on this topic. Wrong perhaps, and by your choice this would be an error that would not go resolved through discussion for fear of the possibility of confusion? I fail to see what "confusion" has to do with it - except for the respondent.

This is trivial perhaps, I would allow that as a criticism (and I think that is the gist of your response). However, to dismiss this also dismisses other discussion that relates, and is in fact another of Punchinello's favorite gadflies: that the antenna radiates from the

entirety of its structure. I agree.

The common discussion here is that it only occurs at Current Maxima. That serves much discussion, certainly, but it hides the important fact that all such analysis is ultimately derived from ray-tracing from the entire structure, and is not the simplistic one-note song of nodes. Given this bias of thought, it becomes even more confusing (another irony) when the discussion of how elements of a beam contribute to the construction of the radiation lobe (one of the least discussed issues here). To ignore the components of the standing wave in the radiating structure is one thing, to expect they not be considered out of fear of confusion is another. Ignoring such considerations serves a lot of answers faithfully. Expecting a moratorium of discussion snaps the rug from under that faith.

What Doc sez is true - about a month ago I ruined a screwdriver that had a PVC coil form while
running at the 500 watt level on 40 meters. 100 watts will undoubtedly present less heat, but if you
are going to use that type of material, use the grey stuff with a thic a wall thickness as you can
find - it's commonly use for electrical conduit, and is lots more resistant to heat distortion...

Hi Charles,

I find this a curious form of touting advances in e-anything only to
reveal the ignorance of e-security. In other words, if it is such a
good idea, why wasn't it fully thought through?

The issue of faking anything is resolved through electronic
signatures, not photocopies of licenses. Honesty and integrity need
not be tested when solutions are available to answer that now.

The ARRL is hardly the bastion of new concepts. It is obvious that if
they were, they would be the repository for Digital Certificates in
this matter and others. Instead of being ahead of the curve, they
fall far behind the electronic signature bill signed by Clinton (this
serves to illustrate the severe time lag - nigh on to two years).
Unfortunately this also illustrates the gerontocracy that seems to
have ossified the organization.

Hi OM,

Obviously you have not flown into fog drenched SeaTac (Seattle-Tacoma)
on United. SeaTac IS shut down to other airlines who haven't ponied
up the money for new equipment.

The services are there. Expect to enjoy them once the lagging
airlines find a way to call for welfare relief over this "security
issue."

Hello Richard,
How much "security" is really needed for a "hobby awards" program anyway? The eQSL Authenticity Guarantee is quite adequate security for the job of administering "hobby awards"

After all what would - your - damages be if someone cheated their way to DXCC Honor Roll? It sure wouldn't affect my DX credentials..how about yours?

Any and all security measures of any kind can and usually do get reverse-engineered or circumvented in some way. Just look at the software industries decades-long battle with piracy. No more than do they have a new protection scheme than 2 days later the "crack" for it is posted world-wide on the internet.

eQSL security is just right for "hobby awards" and believe me folks...Ham Radio Awards - and - DX are just hobbies....

BUT! It's composition is different and, I understand, contains some
metallic properties that does wierd stuff to a loading coil! I was made to
understand that this stuff is a no-no.

Hi Steve,

It would serve all to consider another form of well specified
radiation.

The noon day sun, at the equator, on the equinox, illuminates a square
meter with roughly 1KW of radiation. Your numbers reveal exposure
nearly 5 orders of magnitude below what would be acceptable to any
Caribbean vacationer. A one week cruise (with only one hour's
exposure each day) would equate to roughly 100 years of constant cell
phone transmission exposure. There won't even be tan lines to worry
about, much less a sarcoma.

There was an article in the Houston paper a couple of years ago about a family
that was terrified of the cell tower that had been placed in their neighborhood.
According to the phone company, the transmitter was at the 25 watt level. Don't
know if all cell towers transmit at that level, but you probably have more to
fear from your vertical and g5rv.

Hi Richard,

Good point.

Its funny how people perceive things they don't understand. Most people would be amazed as to the level of RF that surrounds them from countless sources - not that much of it is significant. We went through this in our town recently when one of the carriers wanted to put up a cell tower. People that panic about cell phone "radiation" gladly lie down on a bed at the local tanning salon and merrily shower themselves with daily doses of UV - gotta look good on that vacation.

Take care,

Steve

>A microwave link would be of more concern, but again you would have to >be a few feet directly in front of the thing.

Actually, analysis of microwave parabolic reflectors shows you'd need somewhere around 50 watts of power going in to an 8' dish to reach ANSI limits anywhere in front of a radome.

I can tell you with good certainty that it's indeed rare to use that much energy on a terrestrial link. We have 15 mile paths with huge fade margins and a 10 MHz wide signal and we only use 250 mW.

The size of the dish is usually mandated by the need for narrow beam widths --not signal strength.

/* Begin Rant */

I had a hoot with those FCC regulations too. The place where I work had a few rooftops where antennas could be accessed by plant personnel and I had to show that there was no danger.

The one and only place were I could find a hazard was if someone climbed inside the radome of the dish and stared right in to the feed-horn. Nevertheless, when some roofers came through to do work on the building where our dish was mounted, they refused to work unless we could get the microwave station turned off.

We gave the project manager hell for agreeing to this without asking us first. We asked him: which is less safe? Exposure well below ANSI limits; or shutting down, police, fire, telemetry, and telephone traffic from that area? Anyhow, we shut the thing off for 30 minutes so these wankers could get the job done. But while it was shut down, one of our staff went to the roofing foreman and pointed in the distance to another dish. "See that?", he said. "That dish is pointed right at this one. This dish is off, but that one is still beaming you right now. You didn't ask us to turn it off, so it's still on. Have a nice day!"

Even to this day, we still have bogus warning signs near our dishes to warn away the unwashed idiots who make policy all over this. There is no use explaining what ANSI limits are all about or what the term Non-ionizing means. Ignorance and stupidity are the ruling factors here.

/* End Rant */

Hi Stan,

I hope you are not using Romex wire. Throw it all away and go with MC wiring. The galvanized steel jacket is best but the aluminum is a close second for shielding. Romex wire acts as a giant antenna for noise any and all. Usually the wire is long enough to pick up nearby lightning strikes and send that energy into all of your household items that are plugged in. The MC wire that is galvanized steel works well against magnetically induced noise (H field) as well as electrically induced noise (E field). The less expensive wire which is aluminum MC is only effective against electrically induced noise. Two panels is a complete waste of time and money. Put your time and money into using the right materials and an effective grounding system. More noise from switching and motors is the result of a bad or poor ground. Make sure you use a lightning protector at the main panel and Triplite noise/surge protectors at every electronic device in the house. You will not have any noise problems or lightning issues. Remember to use only shielded wire for everything in the house. This includes heating system low voltage wire, phone lines, RG6 for cable TV, door bell wires, and last but not least the garage door opener sensors and button wires. If you forget anyone of them, noise and lightning will remind you soon enough on a mountain.

Good luck,
Frank (N1SIF)

Thats what I was thinking. The main impact to him will be he will have a new lightning rod across the street. I have one about 3 blocks away. It takes hits fairly often. Your nephew shouldn't be having problems though. He's doing something wrong with his wiring/ suppression scheme to keep having repeat damage from a strike that is across the street. He shouldn't be having any problems unless the cell site is not protecting their power or phone lines. And this is sort of unlikely or they would go offline with every strike. "I have to assume it's coming in on the power or phone lines as a surge"?? He should be able to protect his gear from that. Sounds like he may not be using a single point "star" grounding system. One reason this doesn't really seem right to me, is I've taken hits on MY mast 15 feet from where I'm now sitting, and never had any trouble like that. He shouldn't be having trouble with one across the street. Also, it's quite likely the cell tower is a good conductor to ground, so most of the strike should be going to ground at the cell tower. There should not be much energy left to cause all that damage elsewhere. Somethings not right somewhere...And I bet it's at your nephews house with his grounding/suppressor setup. MK

I put in a single 350 amp feed underground to service panel when we build 13 years ago. From the service panel I feed 100 amps underground to my barn. Even arc welding in the barn or use of other high wattage items in the barn cause no voltage drops of noise problems at the house. I wired any watt hungry items with the next largest gauge wire above recommend size (30 amp load I used 8 ga instead of 10). This got rid of any voltage drops when these items start. For the wiring that went to my radio room, I took a path that allowed me to stay as far away as possible from other general house wiring. Stay away from the high wattage wiring as most of these watt hungry items have thermostats that have point contacts for switching. For the 220 line to the radio room I used shielded entrance cable, splitting off 220 for the amp and 2 110 lines. I never get noise from any motors or heat elements. I do get a little noise from the microwave at times, the monitor for the computer here in the radio room is my biggest RFI producer.

Richard,

Sorry for the response as "Joe". I just "upgraded" to Outlook Express 6
this week and have been having some real problems. I set up another account
with a quick alias of "Joe" to check the downloads and forgot to set the
alias back to VE9SRB before responding. I'm having some major problems
downloading messages with this version. Oh well.

Take care,

Steve VE9SRB

I havnt heard of that, but Ill ask my tooling friend. Finding
Fiberglass tubing is a Beaaach too.

I was trying for Phenolic and or fiberglass but here in the PNW there
doesnt seem to be a listing of this kind of material.

Off to search for Nylok

3210. Email from ARRL - President about eQSL's

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-14 21:24:12 UTC
From: Charles Johnston <ctj92@cableone.net>
Message-ID: <3c6c2afa$1@news.bnb-lp.com>
Source record: 148648
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment

Hello interested Hams...

I have had some interesting, courteous, and informative emails with the ARRL president Jim Haynie, W5JBP concerning the recent flap about eQSL acceptance for DXCC.

Jim was also nice enough to forward to me in-house ARRL email from Bill Moore to Jim which goes a long way to further explain the likelihood of eqSL cards being accepted for DXCC as eQSL web site now states. Jim has asked me not to include the actual verbatim email from Bill..but has encouraged me to post "just the facts as Bill has laid them out" (Jim's words to me) .... and so to the best of my abilities I'll do that now....if you want to skip ahead I can tell you it still looks like eQSL cards can be and will be accepted by the ARRL as long as some important steps are taken....

Here are cut and paste excerpts from Bill's email to Jim....
---
1. It seems people have not read the entire message, especially the part that says "acting as QSL manager". On his site I see where he has OK for sending e-QSLs, not paper QSLs.In
order for us to accept anything from him we would need a letter from each
station he "manages" authorizing this

2. Then, we'd need something better than his word that he is verifying logs each time a request comes in (something we do not think he will be willing to do with all the stations he has logs
for).

3. The requesting station must send information listing the specific QSL information then the
manager must check the log for it. I believe the term for not doing this is
pre-emptive QSLing.

4. As I have mentioned to all who have written, that ARRL has not changed its
policy in any way regarding electronic QSLs.

---
end of cut and paste.....

Because it will take more than the combiner with ferrite isolators to do the job. He still has to notch TX noise from TWO transmitters--that's at least 8 notch cavities on the transmitters-- just to protect the two receivers from TX noise. Add another 4 cavities on each RX port to notch the two TX signals. Getting kind of big...

>
Oh no, please not the "effective radiated power" fallacy again!

I hate to see RF engineers quoting ERP in connection with RF hazards,
because it produces misleading results, and generates big numbers that
only confuse and frighten people.

Remember that RF hazards are related to power DENSITY in watts PER
SQUARE METRE. If you feed 1 watt into an antenna with an aperture of say
1 square metre, the power density is 1W/sq m (assuming uniform
illumination, and neglecting near-field effects for the moment). If you
increase the aperture to 2 sq m, you increase the gain by a factor of 2
and you double the ERP - but you have HALVED the power density across
the aperture.

Near-field effects and non-uniform illumination may change the minor
details, but the big picture is that the larger the antenna, the SMALLER
is the power density for the same amount of power.

And no matter how high the antenna gain is, you still only have the same
amount of RF power you started with.

ERP is only about long-distance communication effectiveness - it has
NOTHING to do with RF hazards.

As the clock ticks over from 8:01PM on Wednesday, February
20th, 2002,
time will (for sixty seconds only) read in perfect symmetry.
To be more
precise: 20:02, 20/02, 2002.

It is an event which has only ever happened once before, and
is
something
which will never be repeated. The last occasion that time
read in such a
symmetrical pattern was long before the days of the digital
watch (or
the
24-hour clock): 10:01AM, on January 10, 1001.

And because the clock only goes up to 23.59, it is something
that will
never
happen again.

And considering the typical electric fence operates at 5000-10000
volts, how many kilowatts are you pumping thru that dipole?

I'd think the electric fence porcelain insulators to be good for
most amateur uses.

The service certainly is available. There are a number of airports in
Europe that are rated "zero-zero". Aircraft that are properly equipt
can land at those airports with zero visibility. This capability has
existed for many years.

The problem is getting the FAA to spend the money out of the massive
airport improvement fund to upgrade the major US airports. It would
also be necessary to get the aircraft upgraded and pilots certified
to land under such conditions.

Will,

I don't recollect ever hearing the term "binding posts" mentioned on the air in the UK.

I remember it from American radio books (recreational, make your own radio receiver) prior to the 1950s and I guess most old timer Gs are familiar with the term.

Mantenance instructions handbooks which came with American radio and radar equipment 1942-45 used the term.

Over here they were known by the more mundane name "screw-terminals". 1920-40, all-brass, no insulation, intended to be bolted through ebonite panels. Baseboard and back-panel connections were made with square brass wire. All changes in wire direction were at the mandatory angle of 90 degrees. Havn't seen any for many a long year. If only I had kept a handfull!

Christmas Day 1994 more or less never happened for me. I was on a Japan Airlines 747 heading West. To a fairly high degree of accuracy (based on the navigation screen that they show after the movies are done and having nothing better to do but pay attention to such nonsense) we hit the International Dateline at just about midnight on 24 December 1994.

Within the accuracy available to me at the time, it could have been bang on. It was certainly within a very few minutes.

Yep. I installed a 900 MHz trunked radio system for a business here in Oregon. There was a woman on the top floor of the building that was concerned about the exposure to RF, so the Environmental Health and Safety people got in touch with me to check it out. They brought their super expensive field strength equipment and we checked the signal intensity. They could not get any meter indication at all while standing on the roof of the building - and no indication inside the building. They could get an indication if they held the probe close to the antenna.

On the other hand, they checked the woman's cell phone, while she was using it. That gave a quite measurable reading - still so low that it is considered harmless, but orders of magnitude higher than what she was getting from the trunking system. I am glad we tested the phone, as that shut her up. Like a lot of people these days, hazard depends on how "important" something is - and having a cell phone against the side of your head for hours on end every day seems to be "important".

There must be something wrong with his suppressor installation.

If "point of use surge suppressors" are what I think they are, that is
most likely the problem. He needs the suppressor ground to be at the
same potential as the phone system ground and the house ground. This
is not accomplished by plugging a suppressor into the wall and then
plugging the router into the suppressor.

For Sale:

Discone antenna. Was installed for a very brief period of time (couple days tops). Owner took it down to erect a vertical. All appears to be here. It appears to be in pretty good shape. It is "similar" to the present model sold by Radio Shack for $59.95. I believe this to be a "former" model.

Shipped and AS IS - $30.

Note that this applies to ordinances. It does not apply to CC&Rs.

It is pretty straightforward. It says that the local governments and government agencies are limited in how they restrict amateur antenna installations.

It does not deal with CC&Rs, which are not ordinances. They are contract clauses made between the buyer and the homeowner's association having enforcement rights.

Isn't it possible that EM can be coupled into the house bypassing the main entrance ?

A few years ago, I had a good-sized lightning strike on a tree about 200' away from the house. The tree, a huge old pine, was split in half. Some of the damage in the house was more associated with direct pickup (on long wires runs INSIDE the house) than with anything entering through the service entrances.

I guess one should treat long wire runs as if they were antennas (since they are...).

Funny. I would think that 21:12 21/12 2112 would qualify.

Ian, G3SEK wrote:
"ERP is only about long distance communication effectiveness - it has NOTHING to do with RF hazards.

Effective Radiated Power (ERP) increases power per unit area, the same as higher transmitter power does. This works just like the flashlight (electric torch?) reflector concentrates the feeble light output of a tiny lamp into a bright beam.

There are directional antennas which concentrate power into a narrow beam. The measure of power concentration is the ratio of maximum radiation intensity of the directional antenna in a particular direction to the maximum radiation in the same direction from an isotropic radiator.

The effective power increase produced by antenna gain is just as real as that produced by an amplifier. There is no way a receiver can tell the difference.

One watt radiated by an antenna with 30 db gain produces the same signal at a given distance on the beam of that antenna that a 1000 watt signal transmitted from the same site by an isotropic antenna would produce.

So, a one-watt transmitter can produce an ERP of 1000 watts by using a 30 db gain antenna. Anything in the beam of that antenna is affected the same way as if it were irradiated by 1000 watts from an isotropic antenna at the site of the gain antenna. ERP is valid and useful.

Screw terminals work by screwing a threaded rod into a tapped hole in a
piece of metal. The hole is fixed and the screw is not. A "Binding Post"
works by turning a piece of metal with a threaded hole in it onto a
threaded rod which is fixed. They are different but do the same job.

>
There's your problem: that statement is only half-true.

It is only true at normal "communication" distances - hundreds,
thousands or millions of wavelengths away from the antenna. At these
distances the inverse square law applies, so the power density is
continuously decreasing with distance. Although a receiver can detect
the signal, the power density is always far below hazardous levels.

In contrast, RF hazards only arise close to the antenna, where all the
taken-for-granted assumptions of RF communications engineers cease to
apply.

Let's look at that statement again, but this time close to the antenna:

>The effective power increase produced by antenna gain is just as real as
>that produced by an amplifier. There is no way a receiver can tell the
>difference.
>
When your receiver is a field strength probe, making RF hazard
measurements close to the antenna, that statement is very obviously
false. For the same power level, you will get SMALLER field strength
measurements around a large antenna than you do around a smaller one -
simply because the RF energy is spread out over a larger area.

Power density - the measure of RF hazard, in watts per square metre - is
roughly related to the square of the field strength (V/m) [1].

For example, when surveying a microwave dish, you find the biggest field strength is right at the mouth of the feedhorn, where the available watts are still concentrated into the smallest number of square metres. Obviously the power density here does not change with the size of the dish.

Elsewhere around the dish, for example at the edges, you find LOWER power densities for larger dishes. The available watts are spread out over a larger area, so the watts per square metre are reduced.

There is another place where RF hazards have to be considered, which is on the axis of the beam, just where the near field is transitioning into the far field. Here you may find a power density peak... but beyond that the far-field inverse square law takes over, and power density drops off as the square of the distance.

It is perverse that some RF communication engineers, who are generally all for promoting the safe uses of RF, seem to be absolutely determined to shoot themselves in the foot on this issue. (I am not picking on Richard individually here - he is far from alone.) The reason is simply that very close to the antenna, their everyday knowledge breaks down.

For anyone who still can't accept this, an internet newsgroup is the wrong place to run a detailed tutorial. The subject is very well covered in any book on RF hazards, including the ARRL book, 'RF Exposure and You'.

[1] In the near-field of the antenna the E and H fields are not in phase, so assuming that power density is proportional to the square of the E or H field strength will tend to over-estimate the hazard. This is normal prudent practice in hazard assessment.

It is only interesting until you think about the artificial constraints
we place on such series.

For example, in the one I listed - we use the European date notation.
If we use the American date notation, with the format given, then there
can never be another date that fits. And the last would have been in
the year 1221. Note also that, using the European date notation, the
one I list above is the last one possible in that format.

Your series falls apart if we use the proper 4 digit year.

> > than with anything entering through the service entrances.
>
> How do you know it was picked up by the wires and did not
> enter through the electrical service?

Well, obviously I don't "know" (for sure)... ...but 'the evidence suggests' that it was coupled directly. One household wire (only one) got burnt and ended up being shorted at the outlet box. This one wire was the longest such wire run in the house. There was no other damage associated with the household wiring. The lightning hit a tree near the lake, no where near the power wires.

I don't believe that lightning damage is necessarily confined to path taken by a single bolt. The lightning bolt is one side of a transformer. The secondary windings are everywhere else in the neighbourhood. My coworkers was watching lightning hit the lake in front of his house and he got a spark on his foot from the metal heating duct when a huge bolt hit the lake a bit closer to his house.

It shouldn't be a controversial suggestion that EM can travel through walls made of wood and drywall and then be coupled into long conductors. After all, most radios that are damaged by lightning are not in the main path (and vaporized). Their antenna or lead-in cable just picks up sufficient EM to pop a few circuit elements.

My point was that you might need to put suppressors elsewhere than ONLY at the service entrances. Unless your house is a Faraday Cage (aluminum siding perhaps). If you have long wires being run around inside your house, they will pick up energy just like an antenna. You would need to put some suppressor at each end of any such long wires.

There is too much focus being put on protecting 'The Entrance'. Commercial building are often made of steel (Faraday Cage). Houses are usually not made of steel and are therefore transparent to directly coupled EM on internal wiring.

That's the difference that seems to me to be often overlooked in such discussions.

Translating the approach that works in the commercial world to the household world, I have never seen this obvious difference explicitly mentioned.

>If you
> increase the aperture to 2 sq m, you increase the gain by a factor of 2
> and you double the ERP - but you have HALVED the power density across
> the aperture.
>

Power density across the "antenna aperture" is not the issue. The issue is
not how the total power is "distributed" across the antenna. The issue is
how the antenna "distributes" its total radiated power in space. The
antenna's gain and pattern shape are the important parameters to consider.

You forgot to consider the relative distribution of the total radiated power
in the far field. With the antenna having a 2 sq m aperture you may have
decreased the power density at the aperture by a factor of 2 but both
antennas still radiate the same total power - this does not change. Now,

with the 2 sq m antenna (assuming you doubled the aperture dimension in one direction), the pattern beamwidth of the antenna decreases by a factor of 2. So now you have the same total radiated power concentrated in a narrower beam (that's why the ERP increases), its also why the power density in the far field from the 2 sq m antenna is greater than that of the 1 sq m antenna.

You're confusing people by telling them that a bigger antenna with more gain has a lower radiated power density because the power delivered to it is spread over a bigger antenna size. Your discussion would lead people to believe that they are safer standing in the main beam of a 100 dB gain dish than a 1/2 wave dipole.

Nothing. Bill, these folks had been watching too many Star Wars
movies where death rays came from dish antennas. Andrew Company's
logo doesn't help this situation much. We actually ordered our dish
antennas without the logo so that it wouldn't scare so many people.

And besides, we didn't lie to them. We told them the truth, and we
stood outside with them the whole time, waiting for them to clear out.
So they must have understood that if we were going to stand there with
them, we didn't think there was much harm. Keep in mind, these folks
were in the commercial roofing business, so they must have seen radio
antennas before. If they can't understand the hazards, they shouldn't
be there.

I can tolerate stupidity and ignorance among those who normally would
never see such things. But if you're in the business, if you're
someone who carries certifications of one sort or another, I have no
mercy whatsoever. If they don't like it, they can always do something
else.

Ian, G3SEK wrote:
"There`s your problem: that statement is only half-true." (There is no way a receiver can tell the difference between more power from an amplifier and more power from antenna gain.)

Ian explained that a given power irradiating (illuminating) a high-gain antenna reflector produces fewer watts per square mtr on the large parabolic reflector than the same power illuminating a smaller, lower-gain reflector, in watts per square mtr.

Seems obvious. Same watts on a small area produces higher intensity than the same watts spread over a large area. Ian is correct in this.

There is a 23-cm ham band shown as extending from 1240 to 1300 MHz by my ARRL Handbook. 23 cm is 9 inches. You have only to be about 4 feet away to be out of the induction field (near-field), by most definitions, and into the far-field at these frequencies.

No one is going to be residing in the near-field of a microwave dish.

Ian also said:
"It is only true (No way a receiver can tell the difference.) at normal "communication" distances - hundreds, thousands, or millions of wavelengths away from the antenna."

Our FCC uses "Ground Wave Propagation Curves, 540 KHz - 1600 KHz" (my copy is very old) based on field intensity at one mile.

One mile is about 3 wavelengths at the lower frequencies covered by the curves. It obviously has been distance enough for far-field measurements for 68 years. The Communicaions Act of 1934 established the FCC as I recall.

Richard's statement is true a lot closer to the antenna than hundreds or
thousands of wavelengths.

And yes, at communications distances, the power density is far below RF
hazard levels.

> In contrast, RF hazards only arise close to the antenna, where all the
> taken-for-granted assumptions of RF communications engineers cease to
> apply.
>

Why do you assume that RF communications engineers don't understand what
happens close to an antenna? The original post referred to a situation
where the observer was 75 yards away from the antenna. The responses
discussing ERP and relative power density were based on that assumption.
There was no need to compare the RF hazards at 75 yards with those at 1
foot. We all know they are different at these distances. Had the original
poster said that he intended to climb the tower and rest his face on the
antenna radome, he might have received a different response.

Most RF engineers understand that antenna pattern, gain and ERP are not
relevant in the near field of the antenna. That however, was not the basis
of the post or the subsequent discussion.

> Let's look at that statement again, but this time close to the antenna:

Again, the discussion and responses were not made based on a near-field
probe of the antenna.

>

You measure a LOWER power density simply because the edge of the larger dish
is farther away from the feed horn. To turn this fact into a statement that
larger dishes present less RF hazard is absurd. For a large dish or a small
dish, the near-field strength along the dish surface is nearly the same when
the measurements are made at the same relative distance from the feed horn.

The important issue regarding near-field RF Hazard and a dish is how far you
are away from the radiating source of power.

Stand at a fixed point somewhere between the feed horn and the dish. Does
the RF hazard diminish if you double the size of the dish?

> There is another place where RF hazards have to be considered, which is

It's amusing that you entire discussion is based on an assumption that an RF communications engineer would have never guessed that at the edge of a large dish you measure a lower field strength than you do at the edge of a small dish.

I think the surge is coming in on the phone lines. The tower was
originally built for use with a FM radio station. Once the radio
station moved closer in to Austin, the tower was leased out to a
number of users including the 800 MHz trunked system for the county
emergency services.

All of the trunking equipment is located out by the side of the road
near the base of the tower, and the phone lines run right next to the
trunking equipment. I'd be surprised if there weren't several lines

connected to the trunking equipment. I'll have to ask my nephew where his phone line surge suppressors are located. His house is wired with all phone lines and network cables tied in to a patch panel in his server closet.

Regards,
Ed

I`m amused that Ian picked on a guy who has measured the illumination of dishes and periscope reflectors.

With a periscope, you collimate the beam with enough directivity so that the reflector catches nearly all of the beam. You also adjust the reflector to be slightly concave (checking for maximum signal) to refocus the beam exiting on the horizontal. A field strength indicator helps determine that the beam is centered on reflectors, but the ultimate indication is limiter current in the receiver.

I used a framing square across the edge of a dish to sight the reflector for initial set up, usually. I also usually used a bubble level to set the "fly-swatter" on the tower to 45 degrees. I`d lay out the azmuth with a transit, putting stakes in the ground to sight so as to set up the reflector. I digress.

The average power density on a reflector is usually straight forward. It is not uniform. It does fall off at the edges, but you know the power and the area it illuminates.

Since antenna gain and pattern shape are determined by the field
distribution (i.e. the specific power density) of an aperture antenna,
all the parameters listed above are equally important.

Assuming the same input power for both antennas, the correct answer depends
upon where your standing.

The "correctness" of our statements always depends on the perspective from
which they are written or read. We could play that game all day long.

I don't really disagree with much of what Ian was saying. I just had an
issue with the "Oh no, please not the "effective radiated power" fallacy
again!" statement and the ones that followed in his other post. He choose
to look at the issue from the perspective of standing within the near-field
of the antenna and then criticized my response for having chosen to look at
the issue from the perspective of standing in the far-field - which was the
basis from which the original question was asked.

Hi Don,
That's correct (antenna mounted center of rollbar & folded with canoe strapped down). I don't anticipate putting up a canoe on any regular basis but want to be capable when I want. There's no flat metal up there but, yes, I could use a mag mount on the hood or fenderwell. The hood's a bad option for me because I don't want to damage the new paint in any way at such an obvious location. My goal was a permanent mount, high and symmetric to the body without having to move it here and there. The 7900's a pretty tall antenna for 2m and they say don't use a mag mount. If I were to mount it on one of the supporting bars of the roll bar, how much affect do you think it'd have on radiation pattern? It wouldn't be parallel to sheet metal. The only metal within two feet would be the roll bar itself.
Thanks to Red Baron for the recommendation for the Diamond lip mount but the Jeep doesn't have any "lips" to speak of. I'll basically weld a horizontal steel tab (1" x 1") that I can mount in like through the roof of a regular auto.
Best Regards,
Drink, WP3JQ

Second that! Why not worry about the volcano under Yellowstone? It's past due to erupt - in fact the ground above it is already rising - and the last one like it, only 1/3 as powerful, brought man within 2000 souls of extinction. Or one could worry about an astroid hit like the one that killed all the dinosaurs. Or ..... whatever. But please excuse me from the fun. I got important things to think about .. like where to get the $$$ for a new radio ;o).

When my Elmer retired he moved to a place in the Ozarks where he said there were some extremely impressive thunderstorms. On several occasions he saw ball lightning come out of his wall-mounted telephone and roll across the bedroom floor during a storm. Made a real impression on him.

Steve Miller, N8SM wrote:
"Assuming the same input power for both antennas (large and small), the correct answer depends upon where you`re standing."

That`s where we started. It was there that Ian muddied the water by saying the small dish has higher energy density at its surface, which is specious.

The larger dish has sharper focus. The beam of all dishes spreads. The spread angle of the larger dish appears to have originated at a point farther behind the dish, so that its beam spreads less in front of the dish. The sharper focus produces a smaller energy spot at a distance. A graphical representation makes clear that this distance is small.

Same power, smaller spot, means the larger dish has the higher power per unit area out there on the path, where there may be someone or something to be exposed.

The near-field argument is specious too The near-field extends only a few feet, at most, for microwave frequencies. Nobody is there long enough for exposure danger.

I could say that when the path length to a point on the center of the beam differs in distance from the emitter by 180 degrees from the path length to a point off to the side of the beam center, their energies are out-of-phase. But, that would be specious too.

Best regards, Richard Harrison, KB5WZI

Hi Drink
What type of Jeep do you have ?Wrangler or Cherokee
I have a 7900 on Wrangler and also have a 7500 on a pick up truck (both fold overs).
I will elaborate upon your reply.

Hello again
I am using the 7900 on the wrangler only for its length.It is mounted on the spare tire bumper bracket which is next to the rt. tail lamp.Being mounted that low the length makes it reach about 18 to 24 inches above the roof height.I have a hard top.
As far as performance I can't distinguish any difference between the 41 inch 7500 model which is mounted
on a 6 1/2" Diamond mag mount which is designed for that antenna.That is used on the roof of my pick up truck and previously was on the trunk lid of a Cavalier Superb performance on all applications.Wouldn't buy anything else.
I had a bad experience with the 7500 when I had it on the roof and went into a very low clearance parking garage.the overhead beam was about 18" above the roof (the ant. is 41") It sounded like I took the roof off of the car !! When I checked the ant. and mount (which did get knocked of) I could not find a single mark on it, never mind broken ! That was two years ago and it is still working flawlessly.....what else can I say

Good luck
Den, KB1EKU

This isn't really something I've thought about or dealt with before, but it seems to me that the issue is more one of simple geometry than a near field/far field distinction. The question is how far away from the dish do the emanations from all parts of the dish add up in phase. I'm having a little trouble expressing the conditions in words in a way that's not too convoluted, but let me try. Imagine a straight line drawn from the rim of the dish, across the dish's center to the other rim. Put an observer directly in line with the main beam, at a variable distance from the dish. The observer will see the full gain or power density of the dish if the distance from the observer to all points on the imaginary line across the dish is the same within a small fraction of a wavelength. If the observer is closer than this, then the power density reduction Ian speaks of will occur. Of course there's no abrupt change -- the dilution gets greater and greater as you get closer to the dish.

Let's say for argument that the diameter of a dish is 10 wavelengths. At a distance of 125 wavelengths, the radiation from all parts of the dish will add together with the same phase within 36 degrees. That is, when an observer is 125 wavelengths from the dish, the distance from the observer to the center of the imaginary line is 0.1 wavelength shorter than the distance from the observer to the rim of the dish (an end of the imaginary line). For phase errors this small and smaller, the distance for a phase error of e degrees is about 45 * d^2 / e where d is the dish diameter in wavelengths. It wouldn't be much of a problem to integrate the field strength at a given distance or phase error for a uniform dish illumination to get an accurate idea of the actual field strength, so I'm sure it's been done long ago.

>Besides PVC. Ive seen phonelic

I looked into this when considering different screwdrivers. Phenolic has the best dielectric and RF characteristics, but it is not an easy DIY. Looking at the tables of electrical properties of materials, I concluded that the best DIY was glass-reinforced epoxy.

You could take a PVC pipe of the correct diameter, put a long 1/8" slot in it. Put some chips or a wire in the slot to keep it from closing. Cover the PVC with poly sheeting. Wrap the thing with 2" woven roving tape saturated with epoxy and let harden. Then squeeze the tube (close the slit) and pull out the pipe & poly.

I recently did some research on TV antennas, and the only manufacturer I found selling consumer grade antennas besides all channel models any more is Channel Master. I admit I didn't put a lot of effort into it, but all my old sources are gone, merged, bought out, whatever. Your best choice is to get a cut to channel antenna and install it as high and in the clear as possible. You should be able to get a grade A picture at least 15 miles from the transmitter that way, if the outside antenna is at least above the local trees and rooflines.

Here is a related bit of trivia. There is an optimum spacing between dish and reflector in a periscope system which depends on their sizes, and vice versa.

It comes about because of path length phase shift differences.

From Lenkurt curves for a periscope, a 6-ft dish with an 8X12-ft reflector, separated by 300 ft, gives 39 db gain at 6725 MHz.

The width of the reflector (height of 12 ft, too) is limited to 8 feet because 4 ft from the center of the reflector there is a phase reversal near the outside edge of the reflector. This is caused by a 180 degree difference in pathlength between the ray striking the middle of the reflector and the pathlength of the ray striking the outside edge of the reflector (approximately).

The signal from the elevated reflector would contain out-of-phase energy in addition to in-phase energy were the reflector larger. That would reduce system gain.

So much for trivia.

Best regards, Richard Harrison, KB5WZI

Any outdoor antenna oriented towards the station will make a zillion
percent improvement. Radio Shack has some pretty inexpensive models,
but once you get outdoors the differences between them are minor.

>in the far field.

For all practical RF hazard assessments, the far-field behavior of a beam antenna is irrelevant. All the action is in the near field, and in the transition region before far-field pattern is created.

Let's talk about dishes, although the same principles apply to any "aperture antenna" such as a corner reflector, slotted panel etc. For simplicity let's assume that the aperture diameter D is several wavelengths, so that physical optics apply.

If the whole aperture is illuminated uniformly, with no taper or sidelobes, you can imagine the power flowing out of the aperture in a parallel-sided "tube" which then begins to flare-out into the diverging beam that we see in the far field.

At first sight, the RF power density in this tube is simply the power P divided by the cross-section area in square metres:

Power density = P / (pi * (D/2)^2) = 4 * P / (pi * D^2) W/m^2 (eq 1)
where D is the diameter in metres

Unfortunately this ignores the fact that wave interference in the near field makes the power density on the axis of the beam build up to a peak at the edge of the near field. More accurately, then:

Maximum power density = 16 * P / (pi * D^2) W/m^2 (eq 2)

Distance of max PD in front of aperture = 0.2 * D^2 wavelengths (approx) (eq 3)

Beyond the location of the peak, the power density falls away, and by the time we're truly in the far field it is accurately following the inverse square law.

There are several things to note here:

1. The maximum quoted above is the greatest power density that can be found *anywhere* (unless you actually climb inside the dish and get close to the feedhorn where the power is still concentrated into a much smaller area).

2. The maximum power density is *inversely* proportional to the frontal aperture area of the antenna, i.e. inversely proportional to the far-field gain and the ERP. Let me repeat that: as the size and gain of the antenna go up, and the far-field ERP goes up, the maximum value of power density goes *down* - check equation 2.

3. When you increase the diameter of the aperture, the location of that power density maximum moves further away (eq 3)... but its value gets

smaller (eq 2).

4. Whether or not you need to exclude people from the main beam of the antenna depends on both the RF power and the size of the aperture. Increasing power works against you (obviously) but increasing area works *for* you.

5. (a) If the maximum power density calculated above is less than the Maximum Permissible Exposure limit (for uncontrolled exposure, at that frequency) then you only need to keep people out of the near field and prevent them from actually handling the antenna, or climbing inside it if it's bigger then they are.

(b) IF the maximum power density calculated above exceeds the MPE limit, then - and only then - does the exclusion area have to extend into the transition region between the near-field and far-field.

If the MPE limit is L (W/m^2) then the distance X where the power density falls below L is given approximately by:

X = (D / 2) * SQRT(P * pi / L) wavelengths (eq 4)

Here it becomes true that exclusion distance X increases with D... but *only* if you have enough raw RF power and a *small* enough antenna to be forced into step 5b. As others have said, cellular base stations generally run lowish power into quite large antennas, so they are covered by step 5a.

>You're confusing people by telling them that a bigger antenna with more gain
>has a lower radiated power density because the power delivered to it is
>spread over a bigger antenna size.

Yes, because "the power delivered to it is spread over a bigger antenna size" is exactly what "lower power density" means! (You have a different definition?)

>Your discussion would lead people to
>believe that they are safer standing in the main beam of a 100 dB gain dish
>than a 1/2 wave dipole.

"100dB gain" is inflated rhetoric... but even that exaggerated statement is correct if the ERP, frequency and distance remain the same.

Earlier, you said:

>Before you slam someone on the relevance of ERP, I would suggest you
>understand it a bit more first.
>
ERP is P*(far-field gain) and is proportional to (P * D^2)... agreed, I hope?

You won't see any terms resembling (P * D^2) in the equations above - that's why I say it is irrelevant. Power density calculations for RF hazards need P and D *separately*, not bundled together as ERP.

Bottom line: ERP is meaningful and useful for far-field (communication) purposes, but it is useless for RF hazard assessment. You don't know whether it comes from a large antenna and low RF power (good) or a small antenna and high power (could be a problem). The hazard assessment calculations don't go anywhere near the concept because it is irrelevant.

How about using a cardboard form and covering the coil with carbon fiber cloth you get at the hobby shop strong light durable cheep, good enough for the stealth bomber.... I picked up a roll ready to apply for less than $20.00 including tax. All you need to apply is scissors and a hair dryer..

If the carbon fiber detunes the coils go with the epoxy impregnated cloth. This takes a little longer to cure.

I've finished installation of my IC-706/HS-1600 tuning circuit.
It works like a charm without pushing any buttons on the 706.
Anytime the screwdriver motor is running, the IC-706 automatically
goes into 10 watt CW transmit mode and displays the SWR. Click on
the following to view.

You do good work Cecil. How do you put it into practice? Let's say your screwdriver is tuned to 15-meters, and you want to QSY to 40-meters. I assume you would start the antenna going up, then watch for a dip in the SWR at 40-meters? Short of an Am-Com, this looks like the best solution.

Yep, that's how you do it. Previously, I had to switch to AM mode,
hold the PTT button in one hand, hold the up/down switch in the
other hand, and watch the SWR meter. Now I don't have to switch
to AM mode or hold the PTT button down. It works really well
and is about $200 short of an Am-Com.

Next step is to make the antenna automatically stop moving when the
SWR hits a minimum so I don't have to watch the SWR meter. The
IC-706 side tone will tell me when power has been removed from the
screwdriver motor. I have the design worked out, I just have to
make it RFI proof.

Marvin, W3DHJ wrote:
"Ain`t we talking about Fresnel effects here?"

Yes. That`s it. Fresnel zones are produced by interference between waves which have traveled different distances. These zones form concentric areas around a direction of travel. There is an inner disk centered on the direct ray.This disk is limited by the radius at which a phase inversion takes place. This disk is called the first Fresnel zone. This is like the bull`s eye of a target imposed on a spherical wavefront. Within this bull`s eye, the signal is in-phase.

At the outer edge of the bull`s eye the phase shifts from in-phase to out-of-phase as the difference in path lengths from source to middle of the bull`s eye, and from the source to edge of the bull`s eye becomes 1/2-wavelength.

The target ring immediately surrounding the bull`s eye is called the second Fresnel zone. Signal in the second Fresnel zone is out-of-phase with that in the first Fresnel zone.

SIgnal in the third Fresnel zone is in-phase with that in the first Fresnel zone.

This is a repeating pattern. Odd-numbered zones are in-phase. Even-numbered zones are out-of-phase.

There is a use for this information in path clearance calculations for "line-of-sight" paths.

Best regards, Richard Harrison, KB5WZI

960 MHz is about the lowest frequency at which dish antennas are commonly used. This is a 6wavelength of 31 cm, or 12.3 inches.

By anyone`s estimate, the near field is exhausted within a few wavelengths, or a few feet at 960 MHz.

These microwave frequencies require an almost line-of-sight path which clears all obstructions. Didh antenna paths must clear buildings, trees, hills, etc. This means located well overhead in most cases so that no one can approach the near field. Thus, the near field is not relevant to r-f exposure except in the most unusual cases.

Best regards, Richard Harrison, KB5WZI

Hi Ian,
In another message, you say that "RF hazards only arise close to the
antenna"
This is not true in general, but only when the transmitter power is
relatively low. I don't think you'd want to stand 25', 50', or even
100' in front of a high-gain antenna fed with 1 kW.

In general, the power density in the main lobe of an aperture antenna
is relatively constant (not inversely proportional to the distance
squared) out to the antenna's far-field distance of 2D^2/lambda. With
enough transmitter power, RF hazards could exist at distances ranging
from physically touching the antenna out to the far-field distance and
beyond. If your books on RF hazards don't cover this, they are wrong.

EIRP has *everything* to do with the radiation hazards of aperture
antennas. One way to determine if any hazard conditions exist is to
use EIRP with corrections for near-field effects.

73,
Bill N3WK

An outside antenna - especially one cut for the channel you wish to
recieve, would be far better than the indoor antenna with amplifier.

If you need an amplifier, using one that mounts at the antenna is much
better than one that mounts at the TV set.

I been reading both r.r.shortwave and r.r.a.antenna for a few weeks now and impressed about some of the posters knowledge in this area.

I am new to FMDX and just bought the Arcam FMJ t-21 tuner along with APS-9 yagi antenna and rotator which I installed on the roof 2 weeks ago on a 2 story house. The rotator is made by ChannelMaster and came with a remote.

This tuner does not have a signal meter to indicate the best level for optimum reception. How would I know where to point the antenna to get the best reception?

Is this a matter of locating the transmision tower of every radio station and point the antenna there? Where do I get the info. about their location? Right now I'm getting about 20-30 stations and wish to get more. I would listen to stations from San Francisco (45 miles away) but the antenna had to be pointed the other way around to get the best reception. Why is this?

I'd like to hear some opinion please.

Watt

One thing is for sure...if you have to point your antenna AWAY from San Francisco in order to hear stations there, you are getting a reflection off of something as your primary signal. What is the topography of your area? Are there mountains or tall buildings near you? The only other thing that would explain this phenomenon would be that you are minimizing some kind of interference source or multipath (or possibly overload) by pointing your antenna away from that interference source.

In general, under ideal conditions, yes...you would point the antenna directly at the transmitting antenna for best reception. Your antenna should be quite directional, so if the signal is weak, just a few degrees of antenna rotation should cause change in noticeable signal strength. I'm not familiar with the Arcam, but if it doesn't have a signal strength meter, you have to use your ears and gut instincts to judge signal strength. And remember...maximum signal strength doesn't necessarily equal best reception. Sometimes a weaker signal is cleaner (less multipath or interference). Multipath can cause horrendous distortion on FM if its bad enough. It's caused by the signal bouncing off some object (like a building or hill) then reaching your antenna just slightly later in time than the direct signal. These two signals now have phase mismatch and actually jam one another.

Ian:

I snipped the entire message because I don't intend to respond in detail. I understand your points and I don't necessarily disagree with many of them.

The problem that I had with your responses was that you slammed "RF communications engineers" and the far-field analysis I presented because you believe there is more RF hazard in the near field. You presumed that I did not know what I was talking about because I did not address the near-field issues. The original poster did not indicate that he intended to be in the near-field of the antenna, so why address that aspect of the problem? If someone asked you what the RF field intensity was at 100+ wavelengths from the antenna would you start with an analysis of the near-field distribution immediately surrounding the antenna elements or look at the total power delivered to the antenna, the antenna pattern and the antenna gain? That was my only issue with your posts.

Take care,

Steve

Watt:

Most, if not all of the SF FM stations are on the peak above South San Francisco (I forget the name, but it is a county park). The terrain works against you there, as the various hills between SJ and there are real scatterers, but on the other hand, I am usually able to hear most SF stations down to Mountain View on a car radio, so unless you are in a real deep hole in SJ, you shouldn't have any problem.

See 100,000 watts web page for station locations in the US. That isn't the exact URL, use Google or another search engine to look for broadcast stations.

Now for the part no one will tell you. The biggest problem with FM DXing is receiver front end overload. Local stations will put so much RF into most solid state and many vacuum tube receivers that it will block the reception of weak stations. That may be why you have to aim the antenna away from SF to hear them. SJ stations are likely in more or less the same direction, and you have to move the antenna to a point where they are no longer blocking the front end. Solution? A better tuner like a HK or one of the other tube monsters from the 60s.

You aren't serious, are you??? Those are designed and tuned to two
specific frequencies. They will not allow him to monitor or transmit using
two rigs sharing a common antenna on a local repeater. They would allow two
rigs to
share one antenna, provided both rigs were set to fixed simplex channels
with a minimum spacing (typically 400 kHz or more). There are cheap
"duplexers"
that permit sharing between different band rigs/antennas, but they are
horses
of a different color.

I was planning to put up a home brew G5RV "Jr." antenna, but found that I may have enough long wire for the full-sized horizontal section. Unfortunately, I do not have the ability (at the present time) to elevate it high enough to accomidate the 34' ladder line. Also, I already have a piece of ladder line cut for 17'.

My question is, can you make a hybrid G5RV that has the horizontal length of a full-size (or longer?), mated with a half-sized vertical section? If I understand correctly, the full-size version only uses 16-17' of the vertical section to radiate on some bands, but I have yet to hear of anyone building one with less than 34' on a full sized antenna. I have tried using EZNEC, but it is way over my head.

Thanks,

Allen

> (approx) (eq 3)

There's something wrong with this equation. You can't get wavelengths
out of this equation unless D is either given in wavelengths (you've
already said D is
given in terms of metres) or the equation includes a lamdba term
(D/lambda would be the diameter in wavelengths).

> 5. (a) If the maximum power density calculated above is less than the

> density falls below L is given approximately by:
>
> X = (D / 2) * SQRT(P * pi / L) wavelengths (eq 4)
>

There are a couple of things with your equation that are seriously wrong. First of all, if you look at the terms in the equation the units for X are
length * SQRT(watts*length^2/watts),
or length * SQRT(length^2),
or length * length,
or length^2
In other words X is given in units of square meters. This makes no sense.

Secondly, you can't get the answer in wavelengths unless D is given in wavelengths and L is given in watts per square wavelength. The other possibility
is that the equation would have to have a lambda term.

I suspect your equation should be
X = (D / (2*lambda)) * SQRT(P * pi / L) in *meters* (eq 4A)

The units for X is <metres>, not wavelengths. Put the units in the equation, cancel them where possible, and see for yourself. Run some examples with real numbers and you'll see that X can be a large distance.

Why add the lambda term? If you solve for L using 4A, you get
L = (P/(4*pi*X^2) * (pi*D/lambda)^2
The (pi*D/lambda)^2 factor is an approximate value for the maximum far-field gain of the antenna. L is then the power density evaluated at distance X using the EIRP.

Do a Google search for T2FD. Look especially at W4RNL's site. The antenna was around long before B & W started making them commercially, and there are dozens of variations.

Second step: The T2FD was originally described in a US Air Force publication. Does anyone have a citation for that article (from the 40s or 50s IIRC), or a hard copy they can copy for me?.

Allen,

There's a nice simple little program DIPOLE2 available from website below.
Download in a few seconds. Run imediately.

It analyses performmance, SWR's, radiating efficiency, feeder loss, input
impedances at all junctions, of ANY center-fed dipole + balanced twin line +
balun + coax line + tuner. It even calculates your L-Tuner settings and
efficiency.

With one stroke of a key all G5RV details can be entered for further
experiments. Find all resonant frequencies in a few seconds.

But I suggest you clear you mind of a G5RV and its derivatives. Erect a
centre fed dipole, overall length of no particular value but which fits
nicely into your back yard. As high as you get it of course.

Feed it with ladder line or preferably open wire line of no particular
length right back to the shack, plus, initially, about another couple of
fathoms to allow some later variation in feeder length. (Visit CAM's
website. It is possible to dispense with a tuner and vary line length
instead.

Connect the feeder to a tuner via a choke balun. Avoid coax like the plague
except between tuner and transceiver. And you will have the most efficient
of all the simple all-band antennas which could be erected at your QTH.

Ed Bailen wrote:
"I have lost several modems in thunder storms with no other equipment affected."

I have a similar experience with a clock-radio-telephone combination. I was plugged into both phone and power lines with this.

The phone and power lines share a common ground connection where they enter the premises. Obviously, the potentials of both lines are the same at this point when protection comes into play. Also obviously, the potentials of both lines were greatly different at my device at the instant when the lightning flashed. I would wager that out at the ground rod the volts on the phone and power lines were very nearly the same when the lightning did its thing. This causes me to think the house phone and power wiring acted as an antenna to collect the breakdown volts across my phone-radio-clock combination.

I needed, but did not have, suppressors on the phone and power lines at the device to shunt the device for its protection.

The telcos must have 200 million U.S. customers. For most of their century+ of experience most of their connected subscriber equipment was not also connected to the power line and if it was, protection was provided by the telco. Telcos don`t provide protection for customer owned and maintained (coam) equipment.

Best regards, Richard Harrison, KB5WZI

I don't see why you would care if the vertical part radiated. I
wouldn't really want that anyway. Myself, I'd just string up the
longest wire you can and feed it in the center with ladder line. The
length being whatever it takes to get from the antenna to the tuner.

you need a 6-1 ballun and a 390 ohm resistor, the resistor needs to be
rated
a quarter of your maximum op power.
If you make the antenna a total length of 50 feet and spacing 17 inches
the antenna will cover 40 through to 10 mtrs.

Put out a plea for another broken one -- and piece together the parts...
I did that one time with an old Hy-Gain vertical which came down in an ice
storm. I bought another busted up one at a flea market and made a good
whole one. Worked out pretty well.

Good luck!

Source record: 148506

I can second the info given in other replies.

I had a 'half' G5RV as my first antenna here at 20ft height and it worked
well on 20/40m but not on any of the upper bands. I had a 51ft flat top and
abt 15ft of TV300ohm feeder. BUT the 10/12/15/17 were just quiet. So
following similar advice I put up a dipole 66 ft flat top (that was all the
space I had) and fed it with ladder line bought from the US and went
straight into the transmatch through its internal 4:1 balun.
Well 40 and 20M are just the same but the uplift in performance on the upper
bands is astonishing!
All this at 20 feet but overlooking the beach which helps!!
Good Luck!
Roger

Nope, won't work. On 20m, 102 ft is about 1.5 wavelengths and 28 ft
of twinlead is about one half wavelength. If you halve the vertical
section you screw up the antenna on 20m, the band for which it was
originally designed.

I think the CC dual band beam uses two separate feeds, so you would need to use a dual band combiner to use one shared coaxial feed.

I think the most elegant solution is to use something like the KMA Rover LPY--it will give you coverage from the FM BCB thru 1300 MHz. I am using one vertically polarized for FM work and I love it.

As I mentioned before, I'm working on a better handheld antenna for better performance than my trusty 2m/70cm RD-98 antenna, yet retains much of its convenience. This antenna would have an SMA connector and radials.

The RD-98 antenna is VERY flexible but manages to retain its shape. If you apply pressure to the antenna, you can bend it into a curve. You don't have to worry about breaking it. Although the antenna is 17 inches long, I can compress it substantially. But in spite of the flexibility, the antenna retains its shape. If you let go of the antenna after bending it, it bounces back to its normal vertical shape.

How can I get a piece of wire to exhibit the same characteristics as my RD-98 antenna? The antenna is wrapped in a black plastic/rubber material. I would like the vertical element and radials to have the flexible-yet-shape-retaining shape. Does anyone know what material would give a thin wire (#18/20 solid copper) such properties?

Okay, here's an opinion for you. The pound for pound (read dollar for dollar) champion among modern receivers for FM DXing is the Cambridge Soundworks (aka Kloss) Model 88; its only true rival is the even more inexpensive Tivoli Model One which is reputed to have greater selectivity. The 88 has no signal meter...the Model One has a tuning eye and a sweet gear reduced tuning knob. Presently, the 88 is on sale through CSW for $150. The Model One is widely available for $99. On the 88 I regularly listen to CBC One Toronto which is located a minimum of 105 miles north of me. Some nights, reception is excellent with no or minimal fading; other nights reception is so-so but intelligible. My antenna is a plastic dipole tacked to the bedroom wall on the first floor.

Wow! I didn't know this. Would this secondary reflections be sonically
inferior from direct signals from stations? It would seem to me.

> What is the topography of your area?

San Jose (aka Silcon Valley) is indeed a lowland surrounded by hills
and valleys but not mountains of any great height.

> Are there mountains or tall buildings near you? The only other thing that
> would explain this phenomenon would be that you are minimizing some kind of

I used a 15 ft. pole on top of 2 story house and I don't recall seeing
any obstractions of any kinds in the surrounding area. The only
thing I saw was hills far, far away!

> In general, under ideal conditions, yes...you would point the antenna

It was recommended that I used APS-9 for its directionality. Pls. see
www.antennaperformance.com for specs. I'm not sure if I'm getting
the best bang for the buck on this one.

> I'm not familiar with the Arcam, but if it doesn't have a signal strength
> meter, you have to use your ears and gut instincts to judge signal ...

Ok, thats probably why the meter was not built-in.

> strength. And remember...maximum signal strength doesn't

Source record: 148420

Wow, I wasn't expecting replies so soon! Thanks for all the good input. I could spend days playing around with Dipole2!

I should have clarified my situation a little more. For the time being (possible 12-18 months), I am limited in height (no trees, got to set some tall fence posts)and method of routing the feeder. I was thinking G5RV because, for now, I can roll the coax out to where the antenna will be, connect it without having to get on a ladder, not have to worry about running close to gutters, metal window/door frames, and roll it back up when I'm done. Also, my "starter" budget was just enough to squeeze an MFJ-945E tuner(no balun). I am most interested in 75/40/20m work for now. My goal for now is just to have something to get started with to get on air; When I am finally able to get my shack (er, I mean office in the house addition:) built, it will be on the end of the house where I will have much greater flexibility for a number of better antenna projects.

That may not change anyone's advice, which was all good, and very much appreciated. I just wanted to give you a better idea of where I was coming from with the question.

Thanks again!

Jason Hsu wrote:
"Does anyone know what material would give a thin wire (#18/20 solid copper) such properties?"

Stainless steel is used for its return to original shape, post distortion. If you don`t like its surface resistivity, coat it with copper.

Hi Ben,

Try a T-Pad of three resistors.
R1 27 Ohms
R2 87 Ohms
R3 60 Ohms
is neither optimal nor even available resistor values. However values
nearby (27 Ohms is a standard value, 82 or 91 Ohms, 56 or 62 Ohms)will
come quite close.

connect (using fixed font):
```
____ R1 _______ R3 ___
| | |
75 R2 100
|__________|__________|

Source record: 148426

I just put of a 20' mast mounted via a 3' tripod to my roof. Antennas are performing well. The trouble is, they have only been up since mid-December, and already the tripod is a bit rusty. Now granted, this is Seattle, but OTOH it may be wet, but no salt air, and little ice or snow to occasion the use of rock salt on roadways. Thus I am a bit puzzled why galvanized steel should be rusting, however superficially, in just two months. Is this really normal? I seem to recall some stuff in a spray can that might be of help for this problem, "Galvano-something", basically aerosol zinc. Is that the correct treatment for a rusty tripod?

3339. Two more antenna q's

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-17 09:01:40 UTC
From: tucansam@whodis.org
Message-ID: <a4nrhkgjt1@reader2.panix.com>
Source record: 148427

Thanks to everyone who replied to my "chimney" antenna post a week or so ago. I am still debating what to do, but in the meantime, have two more ideas I'd like feedback on.

As you may recall, I live in a complex with a no visible antenna rule. Right now I can get lots of 2 meter activity with my HTX indoors, so I'm not too concerned about a transmitting antenna. But I would still like to be able to monitor some frequencies, as previously mentioned, nearby ATC, some HF, etc.

As the majority of my free time exists in the evenings anyway, I was wondering about the possibility of building some sort of temporary antenna. I could cut several 6' lengths of 1" pvc and glue mates to one end of each, string coax through the lengths, and then have an erectable antenna I could store in the closet... In the evenings I could get it up pretty high above the roof line and not upset too many pesky neighbors, bringing it down when I am finished.

But how would I support a tall, plastic antenna like this? Even short lengths of thick PVC tend to bow under their own weight. Perhaps there is a better option?

Thanks!

3340. Solid copper

Hi,

My antenna is a wire 5.5 mtrs in length.
It is made of solid 2 mm copper, it used to be an AC lead.

Is this a good material for reception on HF, or does it have to be some
woven construction?

Thanx!

You have absolutely nothing to worry about.

The antenna wire can be of any diameter, size or weight, of any number of strands, insulated or non-insulated, copper, aluminium or brass. For receiving purposes even rusty old iron wire will do.

There's only one consideration - for best performance the length of the antenna wire should not be very short in comparison with the wavelength of radio waves you want to listen to.

Its a good idea for the antenna wire to be longer than 50 metres divided by the radio frequency in megahertz.

For example, if you want to listen to all HF amateur-band frequencies then, for good results, the wire should be longer than roughly 50 / 2 = 25 metres = 80 feet..

A good ground connection is a help. Try connecting to your domestic water plumbing system if you have metal pipes.

R Bigg wrote:
"What I want to do is put one set in the garage and another in the house so I can keep up with the repeater traffic as I walk back amd forth."

First solution would be, one base station connected to your prized antenna, but use as many wired remote control units as you like in as many control points as you like.

Second solution would be, a repeater of your own connected bact to back with the radio connected to your prized antenna. Then use a hand-held radio to control your repeater from whatever point you like. I don`t know if this solution is legal where you operate. It is likely more expensive than solution No. 1.

Multiple radios using the same antenna is likely the most expensive and troublesome solution.

Sorry, typo in copying out the equation late at night - your eq 4A is
correct.

> Put the units in the
>equation, cancel them where possible, and see for yourself. Run some
>examples with real numbers and you'll see that X can be a large
>distance.
>
Yes it can... well, sometimes. Really the only way to approach RF hazard
assessments is by going through a methodical procedure, starting at the
near field and working outwards. The maximum power density is always
expected at the outer edge of the near field, and if the maximum is less
than the MPE limit, assessment at longer distances is unnecessary.

A larger antenna will always make the maximum power density smaller, but
if the RF power is high then the exclusion zone may have to extend into
the far field.

>Why add the lambda term? If you solve for L using 4A, you get
>L = (P/(4*pi*X^2) * (pi*D/lambda)^2
>The (pi*D/lambda)^2 factor is an approximate value for the maximum
>far-field gain of the antenna. L is then the power density evaluated
>at distance X using the EIRP.

Thank you, that's a very good insight.

However, I'm unrepentant in saying that it's a Bad Thing to quote EIRP in connection with RF hazard assessments. You're dealing with non-technical administrators, lawyers and worried members of the public. None of them understands what ERP is, but all of them want to see reassuringly low power levels.

It's always difficult to prepare an RF safety case that non-technical people can understand and accept. In that situation, it's crazy to deliberately and unnecessarily inflate the *apparent* power you're proposing to use. For example, 50W RF and 15dBi can be inflated to 1.6 kilowatts EIRP... yet the safety case is all about what happens to the available 50 watts of RF.

Nobody would expect you to say "1.6 kilowatts" when you could more correctly talk about 50 watts. The result is utter confusion - they just don't know where you're coming from. By the time you've explained that by "1600" you actually mean "50", you've lost their confidence and probably lost your case.

I'm not just spinning scenarios here. I've seen things very like that happen... depressingly often.

All I'm arguing is that since ERP need not be used in RF hazard assessments, it *should* not be used. If I've side-tracked anyone away from that simple point, I apologize.

Allen,

From this and your follow up post I guess that this wire will be only a few feet above ground. If true, this will be a real compromise antenna, but as you say, you just want to get on the air.

I suggest that you consider a trap dipole for your three bands. Forget the ladderline since it is such a small part of the overall transmission line and is way more trouble than it's worth. Traps built from coax are easily made; if you are interested, I can provide references.

Use a balun at the feedpoint (ferrite if you can afford it, otherwise, a few turns of coax) and run the coax to the rig. I know you've shelled out for the tuner in anticipation of needing it for a multiband antenna but it will still come in handy for covering the extreme band edges, particularly 80 meters.

BTW, there is a common misconception, started by G5RV, that part of the "antenna" is "folded into the transmission line." In theory, the antenna is the part that radiates, the transmission line is the part that doesn't. Being transmission line, the vertical section should not radiate.

Welcome to the fold.

73,

Wes N7WS

|I was planning to put up a home brew G5RV "Jr." antenna, but found
|that I may have enough long wire for the full-sized horizontal
|section. Unfortunately, I do not have the ability (at the present
|time) to elevate it high enough to accomidate the 34' ladder line.
|Also, I already have a piece of ladder line cut for 17'.
|
|My question is, can you make a hybrid G5RV that has the horizontal
|length of a full-size (or longer?), mated with a half-sized vertical
|section? If I understand correctly, the full-size version only uses
|16-17' of the vertical section to radiate on some bands, but I have
|yet to hear of anyone building one with less than 34' on a full sized

Nylon is strong, UV-resistant, abrasion-resistant and fairly
inexpensive. I've used 1/8" braided nylon for years with no trouble.
Nylon is a little bit stretchy, so if you need less stretch, dacron
would be a good choice, although usually more expensive and not as
strong. Small boat sailors invariably use nylon for anchoring and
dacron for sail-handling lines, which gives a clue to their relative
usefulness.

I'd avoid polyethylene; not nearly as strong.

Source record: 148440

Hi John,
Very well presented. Your post gave me lot to think about beyond the
normal, tailpipe and ten pounds of aluminum foil under hood (which sounds
more painful than S5 noise:)
Your last statement about the lowest radiators being more significant made
me think about the axles. They're insulated by bushings and the driveshaft
is a slip joint with plenty of grease packed in likewise. My first
impression is that you can eliminate most noise by grounding *everything*
(i.e. frame, body and hinges, tailpipe, axles, drivetrain, fuel & brake
lines, etc). What about ground loops, though? I'm, humbly, a pretty good
mechanic and familiar with automotive electrical systems. However, grounds
loops and the like can tend to pop up from some pretty unexpected places.
What's a good scheme to avoid this? Is it as simple as, "Everything grounds
to frame"? Or, are there other things to think about?
Best Regards and Thanks for the Post,
Drink, WP3JQ

Resistance elements are completely quiet. The fact that the noisey stuff is on a seperate feed helps to supress conducted noise, however you still have radiated noise to contend with. I believe you could do as well with relatively common AC line filters. Usually harmonics of the radiated stuff is what you're fighting.

Hi Folks,
I'm putting up a G5RV inverted V for 40m - 10m and want to avoid TVI for the neighbors. The installation will be as follows:
67' inverted V dipole with the apex at 30'. Feedline is 450 Ohm "window" ladder line down through an aluminum framed window into a MFJ 949E tuner into my IC-730 and RigBlaster Plus/desktop PC.
Understanding that the dipole and feedline will radiate, what are optimum feedline & dipole lengths to avoid TVI to the surrounding neighborhood?
Also, how great an impact will the ladderline to aluminum window frame have?
Any considerations that I haven't mentioned?
I know this is a simple system but appreciate advice and practical experience tips before I put it up and draw negative attention from the neighbors.
73's,
Drink, WP3JQ

Ian, G3SEK wrote:
"All I`m arguing is that ERP need not be used in RF hazard assessment."

No, Ian has argued that field strength peaks near "the outer edge of the near field".

The outer edge of the near field is no more than several wavelengths.

A parabola transmits and receives rays parallel to its axis. These rays all emerge from a focal point or are reflected into that focal point.

The distance between the parabola`s focal point and its surface is variable. It is shortest on its axis.

When we plot a parabola, we know that x is a function of y squared.

Suppose we have a 10-ft parabola (dish) we will use at 3300 MHz. For a typical dish with f/D of 0.4, the focal length (f) is (4)-ft. Think about what you`ve seen. That ratio is about right. That is about how far the feed is sticking out in front of the dish.

4 feet at 3300 MHz is 13.4 wavelengths. The back side of the radiator illuminating the dish is blocked from direct radiation, illuminating only the dish.

Anywhere outside the dish is in the far field.
Concern with the near field is inane.

Best regards, Richard Harrison, KB5WZI

Drink, WP3JQ wrote:
"However, ground loops and the like tend to pop up from some pretty unexpected places."

Only resonant circuits collect and re-radiate substantial r-f. Break up conductors frequently enough with ground connections and the pieces all resonate at too high a frequency to cause problems.

Try the RFI grounding with clip-leads, and you don`t invest too much work in RFI elimination.

Best regards, Richard Harrison, KB5WZI

Hi Ian,

Anyone can relate to the heat of the sun and the common lens.

That same heat through a large lens focused to the back of your head instead of over the area of your body (about that same gain) will teach a lesson that the original, acceptable power is more than lethal, and more than quick (compared to the original exposure) than without that same lens.

Prior restraint on the discussion of the technicalities because some might not get it (the confusion defense) more suggests the speaker is the one with the difficulty, not the audience. It took less than 60 words to express the correlation above in terms that are accessible to every 10 year old student who has already learned to fry ants. Your audience is certainly of greater experience and sophistication and the paragraph above fleshed out with an additional 100 words relating to existing exposure and added exposure should suffice - even for that same 10 year old student who already understands the pain from considerably smaller than lethal lenses.

There is no magic power level low enough to ignore UNLESS there is a corresponding heat (or RF) sink to draw away the power at the load and thus diminish the local peak power to an average region wide distributed load. For the human body, this sink would consist of circulating blood (and air in the lungs) and evaporation from the skin. However, this constitutes very little shedding of excess power in the face of the original KW of heat applied to a region the size of a coin (we are now in the sphere of solar furnaces). This is the point of the limit standards. We are not so much concerned about boiling blood as destroying DNA or disassociating elemental bonds at the molecular scale. A 1 Watt exposure over a sufficiently small space serves to destroy as effectively as a crematorium. You may not die (quickly) as a consequence of a 1 Watt exposure, but your chances (of a sooner death) are elevated out of proportion to no exposure. If you choose to accept the risk, it is only with the tacit understanding that not all destructive exposure leads to consequential damage - this time.

The reason why such standards are expressed in these technical shortcuts of mW/cMï¿½ (which is independent of source, be it magnified or isotropic) is that we can then scale the power applied to the load to determine the probability of destruction (as balanced against the capacity of that load to shed heat, termed in degree rise over ambient temperature for an applied power - otherwise known as thermal resistance).

I would offer one last observation. The heat I speak of can be sensate (that which causes us to feel it and perspire) or be an expression of the energy expended to break a bond, or fragment a DNA chain which is perhaps cooler, but crueler.

Hi Bill,

I have a '98 model Ranger 4X4 and use a Diamond dual band antenna. I mounted the antenna on a "L" shaped bracket in the gap between the hood and the fender. The bracket is mounted to the fender with sheet metal screws and the antenna mounts to the horizontal portion of the bracket.

I have had no problems with noise from the truck on VHF/UHF (I run an Icom IC-W32 HT with a Mirage dual band amp). I also have an IC706MkIIG installed and it works great. The '706's noise blanker kills all of the engine noise. Also, I ran the coax for both antennas under the carpet and out through the soft plugs on the bottom. I cut a hole in the rubber plug to run the coax through, and then sealed it up with RTV.

Good luck,

Bob

Make sure you have a low pass filter in line. That will help with TVI problems a lot. I also have a G5RV installed as an inverted vee and had a problem with RF feedback on the feed line. I did a little research and found a recommendation for making an RF choke out of the feed line just before the connection to the 1:1 balun. You make 6 to 8 loops at 6" diameter in the coax feed line.

Hi Diablo,
I hope we're not confusing antennas. I'm not using coax. Rather, I'm
using 450 Ohm "window" ladder line fed into the MFJ-949E tuner. I'm pretty
sure it incorporates a balun (somebody correct me if I'm wrong). The
original G5RV design didn't use coax. I wouldn't worry much about feedline
radiation from coaxial cable. Hence, my concern about TVI with ladder line.
Thoughts anybody?

Hmm, using the trusty R = E**2/P formula, a 110v (RMS) 250 watt light bulb's impedance should be 48.4 ohms. Maybe not too practical, but just a thought. I used to use light bulbs for dummy loads when I was an economically-challenged Novice.

As an aside, I used to attach neon bulb lamps to the ends of my dipoles just for fun - the neighbors were mystified by my blinking antennas when I was sending CW. For an even better effect, you can hang a florescent light tube on your antenna. Whoa - Stupid Ham Tricks!

The trouble is, the impedance changes with the brightness of the bulb.

There is a major flaw in the lightbulb. It will only be around the 48 ohm value around one power level. If more or less power is used the impedance will be less. Also the frequency will have some effect. If the lamp is used for receiving the filiment will look almost like a short or maybe a small inductor depending on the frequency.

I also think the T2FD needs a much higher value resistor.

I too have loaded into a light bulb before I got a 50 ohm dummy load and watt meter for the transmitters. Not a very good way to go but it will tell if you are putting out power anywhere near what it should be.

As far as the quality of reflected signals, while it would seem that a direct signal would be better, sometimes the reflected signal is better (or the only signal available). Basically, I would rotate the antenna through its complete 360 degrees of rotation listening to the station I wanted to get and choose the best direction. If it is not pointing towards the station, try to figure out what it IS pointing towards. A bit of sleuthing will usually tell you what you need to know.

I looked at the web page for your antenna and it looks like it should be a very nice antenna for dxing. Good directivity. Perhaps the hills around you aren't mountains, but even hills can cause the reflections I think you're getting. Also, the further away the stations are, the closer they are to the horizon, and the more easily hills between you and the stations will disrupt reception. This "line of sight" characteristic of the FM broadcast band causes much problems where I live in the Northeast. it's quite hilly here, and generally FM reception is limited to about 60 miles unless you are at a high elevation.

3372. Return Loss ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-17 21:59:22 UTC
From: Dan Richardson <k6mhe@arrl.net>
Message-ID: <2s807u4qvgt3cktb144quj8t084ohl0uj1@4ax.com>
Source record: 148460

I have been trying to ascertain the value of knowing return loss values. I have checked several books in my library with little or no luck.

Thus far I've checked the indexes in Kraus, Terman and found nothing. In Reference Data for Radio Engineers it is mentioned but the information is given in a section discussing phone lines. The ARRL Antenna Books 18th and 19th editions show a graph for a piticular antenna with no explanation. In an older ARRL Antenna book (published in 1986) gave the most information (a graph, and table listing plus the formula) that I could find.

At the moment I know Return Loss = SWR-1 / SWR+1 and can also calculate the Return Loss in dB.

My question is what is the application(s) of knowing the Return Loss value useful? In other words say I have determined a return loss value of 2.439 (32.3 dB) - now what?

Helping a ham transition out of CB, etc. Right now he is into 2m and 440 so has no need for some items. He has two Antron 99 antennas that can be used on 10 meters, one of them has the ground radial kit. Both have been used but are in very good condition; no instructions but the adjustment rings on the bottom are easy to adjust. He also has a Hustler 5 BTV, it is the 4BTV with the 75/80m optional resonator; used but in good condition; no manual but instructions are readily available on this newsgroup. Finally, he has a brand new, never used, New-Tronics (i.e. Hustler brand I believe) Model 27-TD "Super Swamper" CB base station antenna; included the assembly instructions. Let me know if you are interested in some or all of these. Thanks for reading the posting.

Ian, G3SEK wrote:
"A larger antenna will always make the maximum power density smaller, but if the RF power is high then the exclusion zone will have to extend into the far field."

The smaller antenna`s higher power density doesn`t hold for very far.

1 watt into a 60% efficient dish is 0.6 watt into a cross sectional projected area of 2.63 square meters in a 6-ft dish, or 7.3 square meters in a 10-ft dish.

This produces 0.228 watts per square meter from the 6-ft dish or .082 watts per square meter from the 10-ft dish.

At a distance of 300 feet, an 8x12 reflector produces 39 db gain with the 6-ft dish and 42.5 db gain with the 10-ft dish at 6725 MHz. (This is slightly less than the gain figures for the bare dishes because the 8x12 reflector is not 100% efficient.

Why is the 10-ft dish now producing more concentrated energy than the 6-ft dish at a distance of 300 feet when energy concentration was higher in the smaller dish at the outset?

The 10-ft dish has focused the energy into a smaller spot 300 feet away than the 6-ft dish has. The larger dish gain advantage will hold to infinity.

According to Lenkurt`s charts, it is at a dish/reflector spacing of 220 feet where the intensity of the 10-ft dish surpasses the intensity of the 6-ft dish. These are 6725 MHz data as already said.

Best regards, Richard Harrison, KB5WZI

I once used a network of 2w carbons to obtain 450 ohms at 30 watts. Worked fine with 100w on ssb and cw. RTTY at 100w was a bit much though they didn't fail. Packaged the array in a clear plastic tube 1" diameter and about 8" long.

Unfortunately those 60 words are all about the receiving situation. A transmitting dish does not focus RF energy, it spreads it out before projecting it forwards across its whole area. You're then left with the difficulty of explaining the reciprocity theorem instead.

Leading off with a discussion based on incinerating ants does not look like a good way to get your proposed installation accepted.

The rest of the posting drifts off into "What is a 'safe' power density?" which is not the issue being discussed.

So far, so good... but then:

>Anywhere outside the dish is in the far field.

You forgot the (0.2*D^2 / wavelength) criterion for the near-field distance. (This is based on a reasonable degree of phase convergence between the E and H fields, as Roy accurately speculated earlier.) When you plug in some numbers for large dishes and small wavelengths, the results will surprise you.

Your chosen dish diameter of 10ft at 3300MHz is 33.5 wavelengths. The near field extends out to 225 wavelengths or 67 feet!

The bigger the dish in relation to the wavelength, the farther the edge of the near field. For the 40-footer at 4GHz, where I used to work, the near-field distance is a quarter-mile. Do your own calculation for Arecibo at 10GHz.

Those are the distances where the maximum power density occurs - or rather, where you should start to look for it with a survey instrument (at Arecibo, you'll need a very tall ladder). Although the edge of the near field gets farther way as the dish gets bigger, fortunately the maximum power density gets smaller.

With a real-life dish, it may be more important to look for spillover from the feedhorn past the edge of the dish towards the ground, because people can get to there much more easily. A larger dish produces smaller spillover power densities than a smaller one of the same f/D ratio, as Steve pointed out.

>Concern with the near field is inane.

Responsible RF hazard assessments start with the near field and then work systematically outwards as far as it's necessary to go. Nothing is excluded on the basis of someone's opinion - everything is checked by calculation and confirmed by measurement.

Hi Ian,
I can see where quoting ERP can lead to some confusion on the part of
lawyers and non-technical types. Are you really saying that ERP is not
necessary because, in the types of cases you have experience with, the
transmitter power and gain are both so low that RADHAZ limits are not
exceeded except possibly at touching distances? What happens with a

case where the transmitter power is high enough that the exclusion zone may go into the far-field? You then use ERP? Wouldn't the legal beagles be confused then? Maybe it would be better to come up with a standard procedure that works in all cases. 73,
Bill N3WK

Ok, ok, I give! It was a tongue-in-cheek post, not a serious suggestion. Although I do have a memorable QSO of when I clipped the plug of a desklamp onto the output of my 75 watt CW transmitter to tune up. A guy in Kansas hailed me with a 599 report (40 mtrs, my QTH was Colorado at the time). It was so bizarre that I strung the thing up on top of the house and actually made a few more QSOs on it. I imagine the few milliwatts that were actually being radiated were leaking out of the zip cord. But still, a pretty peculiar phenomenon.

I have a Comet antenna similar to the Diamond 7900 attached to the roof rack on my Dodge mini van. I have whacked tree limbs etc. with it and have yet to bend the mount or antenna. It's been up there for almost two years now using the Diamond K550 mount.

Source record: 148373

Return loss is the magnitude of the reflection coefficient, expressed in dB. SWR refers to standing waves on a transmission line. Often it's imporant to know how good an impedance match is between two networks of any type, not necessarily involving transmission lines. For this purpose, reflection coefficient is more appropriately used and has more direct physical meaning than SWR. And expressing reflection coefficient in dB allows easy expression of a wider range of values than simply expressing it as a number. You'll often see the input impedance of microwave devices expressed or specified as return loss, as a way of indicating the quality of the impedance match.

It's pretty easy to measure return loss or the magnitude of the reflection coefficient directly. Examples of simple return loss bridges are shown in _Solid State Design for the Radio Amateur_ and _Introduction to Radio Frequency Design_, both by Wes Hayward W7ZOI and both published by the ARRL.

Hi Ian,

You seem more intent on your answer than the matter at hand:
> Hi All,
>
> The local cell provider has just proposed putting a 150' cell tower behind
> my house. This would put the tower base at about 75 yards from my house.

> What are the MPE limits for cell frequencies? I know that at Microwave
> frequencies possible damage to eyesight is possible if MPE limits are
> exceeded
which clearly introduced the issue being discussed by everyone else.

You may also note that the original poster disclosed an issue I
DIRECTLY address and to the point of the situation vis-a-vis far field
NOT near field exposure; your characterization:
>The rest of the posting drifts off into "What is a 'safe' power
>density?" which is not the issue being discussed.
not withstanding.

Further, my same discussion illustrates the common experience of EIRP
and it shows quite clearly that what everyone has been saying is
supportable in the experience of children. You don't even have to
discuss the math of focus and curvatures which a child understands
conceptually within minutes of their first association with a lens kit
in the play yard.

Most, if not all, of your discussion seems to be predicated upon much
different matters far afield from the original poster's issue with
exposure. You may have some discomfort presenting the concept with
fried ants, but you have offered nothing in technical rebuttal, nor an
alternative discussion that covers the same issues so called for.

I would hesitate to offer lessons of reciprocity to that 10 year old
student, simply because it is not germane; not because it is difficult
(it isn't); and certainly not because it is above the comprehension of
the student who has undoubtedly already learned that an illuminated
image can be cast through a lens as a projected image. In other
words, even this issue takes far less to discuss than to pine about
the possibility of confusion/difficulty (and no ants were harmed in
the making of that projected image).

If tying to trees and not using pullies & weights, or a length of
bunge, I would use nylon. It will stretch as the trees move. If
there is less that 15' of nylon from the insulator to the tree, I
would leave the nylon slack and put a bungie cord between two loops in
the nylon to take up the slack and provide for tree movement.

|
|My question is what is the application(s) of knowing the Return Loss
|value useful? In other words say I have determined a return loss value
|of 2.439 (32.3 dB) - now what?

Danny,

As you know return loss (RL), reflection coefficient (rho) and SWR are just different ways to express the same thing. Sometimes the context determines the best form to use.

In the laboratory setting, if one is using power meters to measure mismatch, then return loss is what you measure; the ratio of two powers, one forward, the other reverse (and yes Peter, the powers are real). When expressed in dB then you can just add or subtract them like other logarithmic quantities.

If I have a particular load with a return loss of 14 dB and I need it to look like 20 dB, I can insert a 3 dB pad, which has 6 dB RL (3 dB going and another 3 returning) and the composite is 14 + 6, or ~1.2:1 SWR. Similarly, if I have measured a RL of 15 dB but I know the loss in the cable between me and the load is 1 dB, then I know that the load RL is actually only 13 dB. The cable loss makes the load look better than it is. This phenomenon is what makes off-resonant dipoles fed with wet window line so attractive <g>.

In the microwave world you often see device specs like, "Shall be unconditionally stable with a 3:1 VSWR at any phase angle." Going by memory, or my handy H-P reflection slide rule, I know that 3:1 SWR is a RL of 6 dB. So I can test this device by putting an adjustable length short on the end of a 3 dB attenuator and connecting it to the device. By changing the position of the short I vary the reflection phase while the reflection magnitude stays constant.

So in this case (in my mind anyway) it is easier to express 3:1 SWR as 6 dB RL when you're picking the attenuator value.

In your example, by inspection you can imagine whether or not a reflected signal 32.3 dB down from the incident will have much effect on your system.

It should be remembered that all of these quantities are scalar.

So the bottom line is whatever best rings your bell.

Wes

ps. How did you equate those two numbers in your example?

Tom:

You could save yourself some money by just taking a piece of coax and attaching a heavy duty 50
ohm resister to the end of it, submerging it in oil [commonly called a dummy load] and transmitting
on it.

This antenna is a really poor performer. If you find a ham claiming they have worked 200+ countries with this antenna, make a bid for his QTH because he has to be located on an island
surrounded by water or on top of a salt mine. In other words, any good experience with this antenna
is due to the QTH and not the antenna. The terminating resister in this antenna is used to give you
the 50 ohm match, just like the dummy load.

Good luck.

Ian, G3SEK wrote:
"Your chosen dish diameter is 33.5 wavelengths. The near field extends out to 225 wavelengths or 67 feet."

OK. I hope to learn something here.

I thought the demarcation between near and far fields was at a distance from an antenna where the reactive energy was "small" compared with the radiation energy.

Near an antenna, fields are greater iin magnitude and different in phase from the radiated field because the induction fields are there too. The induction fields contain energy to be returned to the transmitting antenna and which is not a part of the radiated energy.

Induction fields fade away very rapidly as distance from the antenna grows. When induction fields are "small" as compared with the radiated fields, the near field ends and the far field begins.

At 1/8-wavelength, or less, from an antenna, the induction field is very strong.

The radiation field contains lines of force which have escaped or broken away from an antenna. An electric field produces a magnetic field which produces an electric field which produces yet another magnetic field. These reproduce each other on and on into space to consist of radiation traveling away never to return, A radio signal.

As I previously posted, medium wave broadcast radiation field measurements begin at one mile or as little as 3 wavelengths, regardless of the gain of the directional antenna array. This is far field measurement.

My memory is vague on the rates of decay for induction fields. I recall that either the electric field or the magnetic reactive field declined as the fifth power of the distance and the other reactive field wasn`t far behind. The power in the radiation field only declines as the square of the distance, as everyone knows. So, it`s easy to see why the induction fields are going nowhere.

Best regards, Richard Harrison, KB5WZI

3392. Re: G5RV Window Line Length vs. TVI

Drink:

First, the antenna you describe is not a G5RV. You are describing a 40 meter dipole with open wire feeder.

There is nothing wrong with such an antenna, and if you plan to operate it on frequencies other than 7 Mhz, the open wire feeder will allow you to do so with mininal problems, providing your tuner can handle the mismatch it will encounter. That mismatch is what the real G5RV design minimizes...the antenna lengths and open wire feeder length keep the mismatches from getting too difficult to handle. If you only plan to operate on 7 Mhz a coaxial feeder will simplify things and make the tuner unnecessary.

Second, your "understanding" that the feeder will radiate is incorrect. An open wire feeder doesn't radiate any more than a coaxial feeder as long as the currents on each side of the feeder are in true differential mode (180 degrees out of phase). That is what you are trying to achieve with a balanced feed system. Does your tuner have balanced output?

Third, I have yet to see it demonstrated that feedline radiation causes more TVI than antenna radiation. I think this is one of the "urban myths" of ham radio. There have been many newsgroup posts by hams with TVI problems and they are consumed with worry about feedline radiation. They should first be sure they are not radiating harmonics from their antenna. A low pass filter is the easiest way to do that. Some tuners achieve a low pass configuration, but many do not--you should not assume your tuner will suppress harmonics. If your tuner is the popular "T " configuration with C-L-C arrangement of two tunable caps with a coil to ground in between you actually have high pass filter with relatively little harmonic suppression.

Lastly, one of the drawbacks of open wire feeders is the need to keep them away from other conducting (metal) objects. But that doesn't mean a disaster will happen if you must run the feeder near some metal. Do the best you can and try it. This is, after all, ham radio.

Good luck and 73,

Roger K6XQ

Are you sure that was galvanized? Even the thin stuff they sell these days should last a year. If it is really galvanized, the sacrificial zinc should hold off general rusting, allowing only localized rust where there is major mechanical damage. Just out of curiosity, what color was it originally, and what made you believe it is galvanized?

I have used "Cold Galvanizing" spray extensively for damage repair, but it has been pointed out that zinc suspended in a binder can't provide the galvanic action necessary to prevent rust in the same manner that hot dip galvanizing does. So, the alternative is several coats of a good high quality outdoor enamel, applied carefully so that all surfaces are fully and completely covered.

Keep us posted on what you find.

Ok, I guess it's better than not having signal at all. The good thing about
rotators is that I can always tweak it for better signal. Surprisingly,
rotators are quite easy to install. Everyone should have it.

Baloney! You have demonstrated a high degree of ignorance
of antennas
with your reply. I doubt if you have ever owned one -- a
B&W Broadband
Dipole that is. I had one for quite some time, and used it
at two different
locations, and had very good results. I've also had
inverted vees and beams,
and although the B&W was down a bit, it provided a number or
good years of
fun on the bands.

It would seem to me that the proper terms to use would be energy density
at given distances - which is precisely what the FCC uses.

There is not ambiguity or confusion possible if a statement is made that
the energy density is (for example) 0.3 microwatts/cm^2. ERP and EIRP
are not necessary. YOU use them to calculate the energy densities, but
do not mention them in the analysis for the non-technical.

The advantage here is that the energy densities can be directly measured,
if you have suitable equipment. ERP has to be computed, based on actual
signal strength measurements made or based on antenna theory.

> volts across my phone-radio-clock combination.

Well, the DC potentials of both the phone line ground and power line ground were the same. There is no guarantee that they were anywhere close to being the same for any given AC frequency. Since lightning is very broadbanded, you can bet that both "grounds" acted as if they were not even there at many of the frequencies generated.

The potentials "at the ground rod" were certainly identical - they have to be, assuming decent connections to the rod. But the further away you get from the rod, the less likely the potentials are likely to be identical.

As far as the two "hot" phone wires and the current carrying power wires, they are never close to being at the same potential. The highest that the phone wires normally reach is about 90 volts when a ring signal is applied.

The lengths of the house wiring for both phone and power are rather small, when compared to all the wiring outside the house. Although I cannot document it, it would appear that the outside wiring would be where the majority of the lightning's induced voltage/current would occur.

In cable tv work we use return loss exclusively for measuring match.
Its a very convenient unit for calculating reflections which will
ultimately show up as ghosting in analog pictures or raise all sorts of
havoc on digital signals.
Ghost reflections can be easily be seen on a TV set at 20-30 db down.
This is in the 1.1 to 1.2:1 SWR range. As you can appreciate, the RL
numbers are simply easier to work with in this case given that the
industry measures in dbmv and the return loss figures make for easy
math.

WARNING

You may be experiencing the differing meanings of near/far field as understood by the US and the UK (simplified demarcation). As a Canadian (stuck in the middle), I get to see both sides :-).

I was introduced to the UK version of "far field" by a very nice lady in Great Malvern, UK that writes some very nice GTD/UTD software. The UK version of "far field" is MUCH farther out than the US version. It is something like where the distance is sufficiently far away that the relative phases of the contributing portions of the overall signal are no longer a function of angle (something like that...).

Perhaps we need to subscript the phase "Far Field" with (US) or (UK)...

I believe that I had detected a third meaning at some point in my career, but I can't recall it right now.

That's precisely why I wouldn't mention ERP under any circumstances.

You rightly pointed out that if (but *only* if) the exclusion zone goes into the far field, then the calculation changes to become based on ERP. The formula involves multiplying the power by the far-field gain - but you still don't *have* to pull out that large number of "apparent watts" as a specific result, and then deliberately make a feature of it.

>Maybe it would be better to come up with a
>standard procedure that works in all cases.

The numbered steps that I listed a few days ago will do that (aside from my typo that you picked up). They address the question "What are the maximum possible power densities at various distances from this antenna, fed with X watts; and if exclusion zones are necessary, how large should they be?" That procedure, with a flow chart, is published in the Safety chapter of the RSGB Microwave Handbook (Volume 2).

>
As far as I know, those general statements are correct. From the RF hazards viewpoint, another way of saying "reactive energy is small" is that the E and H fields are getting close to being in phase (which is generally not true in the near field).

The practical implication is that if E and H are in phase, you can measure either one (usually E-field) and calculate the power density accurately using E^2/377 (or I^2 * 377) where 377 ohms is the impedance of free space. Within the near field that calculation is an overestimate of power density, because of the unknown "power factor" related to the local phase angle between E and H fields.

>Induction fields fade away very rapidly as distance from the antenna
>grows.

That may not be true - it depends on the type of antenna, and each person's individual definition of "very rapidly".

>When induction fields are "small" as compared with the radiated fields,
>the near field ends and the far field begins.
>
That is generally (read: always) valid, though there is no sharp boundary between the near and far fields. Again it depends on a definition of "small", but the factor 0.2 in the (0.2 * D^2/wavelength) criterion represents a widely-used consensus.

>At 1/8-wavelength, or less, from an antenna, the induction field is
>very strong.
>
No doubt, but it doesn't say anything about the distance at which the

induction field becomes negligible. That distance varies with the type
of antenna.

>

They cheated no one. The fact is that you got a great value and no one was cheated.

This issue of spare parts has come up again and again. The answers have been reasonable and consistent from the manufacturer.

Ask yourself the following question: if we hams DON'T buy Cushcraft, then what, exactly is your quality, cost-effective alternative?

The fact that so many Cushcraft antennas STILL EXIST, in PERFECT WORKING CONDITION has created more than a viable inventory of used spare parts; going the flea market or used alternative is not only a good idea, but is a great value.

Frankly, I am surprised that someone hasn't set up their own 'e-bay' on ham antenna parts. There's a small but viable market there fellows.

I have an A4 waiting to go up that's outlasted three owners; 3 radios, and 3 QTH's. How many OTHER parts of a ham station can you say that about?

73,
Chip N1IR

No, it would probably make them worse and destroy the main beam in the
process.

All multielement antennas have sidelobes. Although there are things
that can be done to reduce them, it probably is not worth it.

Yes.

--

On the whole question of balanced/unbalanced tuners, where to put the balun,
etc., etc., see:

http://www.vcnet.com/measures/bbat.html

"Must read" on the whole subject. If you gotta use a lumped-element tuner,
might as well use a good one.

Although the above tuner uses variable inductors, there's no reason one
couldn't use a tapped inductor and a suitable switch. The taps would have to
be found just once for each band.

I assure you I am not trivializing their deaths. I am upset whenever
I hear of decent people losing their lives in an undeserving way.

What I *am* trivializing are the comments about how "hams have died
trying to activate X". The original discussion (a tangent from the
eQSL subject) was whether DXpeditioners lose money due to eQSL's; i.e.
whether they deserve monetary compensation for their efforts. I, for
one, typically send $5 to a DXpedition group when I request a QSL.
I appreciate what they do, and want to help out. That a few DXers
have died on an expedition does not make DXpeditions more noble, nor
does it make them more deserving of cash. It's simply an unfortunate
occurence, like an ice fisherman who falls through the ice or a skier
who hits a tree.

I'm hoping to find some topographic mapping software that will display all areas that are within line of sight of a given point. The principal idea is to use it with VHF and UHF radios to chart out signal propagation via line of sight to all areas around a given point. I'd like to use the software to help me with some "mountaintopping" excursions so I can see where I might reach from a given mountain top.

It seems that the problem is not an overly complex one, but it requires elevation information and a raytracing capability.

I was wondering if anyone knew of any existing software package that will do this -- perferably a modestly priced one. I'll bet that there are proprietary packages that do this and extremely high priced packages aimed at cell phone service providers. I need one that's aimed toward the amateur radio hobbiest.

I have the National Geographic (formerly Wildflower Productions) Topo! series maps. They have all the necessary data in the form of the Digital Elevation Model (DEM) data. They can also plot the elevation profile between two points on the map (along any route). The missing piece is being able to plot the areas within line of sight.

Thank you very much for any pointers.

Best regards,
Pete

Another product, the Maptech mapping software, has a similar 3D
viewing capability. You can pick a viewing spot (the top of Mt.
Whatever), put your viewpoint at ground level, and then see everything
visible from that spot.

I believe there is is a sample available on their website so you could
evaluate it for your needs.

Let us know what ends up working for you.

Thanks for the replies. What the specific differences between a doublet
and a G5RV kind of confused me. Also, I confused what the ARRL Antenna Book
quoted in the initial description. Thanks much for the links and words.
I've a much better basic understanding of the G5RV. Of course, there is one
last thing that might be trivial or just so simple that it eludes me. I say
I'm running a 1/2 size G5RV but others describe it as a doublet. What
differentiates a doublet from the open wire fed G5RV (open wire fed dipole)?
Or is this just a different name for the same animal?

That does seem to be the general consensus. It appears that they don't maintain
any meaningful stock of old parts at all, once they cease a production run.

I've had an R7 and a dual-band yagi from them up for several years, but their
reputation about the lack of service on their HF antennas pretty much guarantees
that I won't be buying another Cushcraft when it comes times to replace the R7.

I'm familiar with that 'discussion' too. Later maybe but better, I dunno.

Varney says such things as:

"As it does not make use of traps or ferrite beads, the "dipole" portion becomes progressively longer in electrical length with increasing frequency.

This effect confer(s) certain advantages over a trap or ferrite-bead loaded dipole because, with increasing electrical length, the major lobes of the vertical component of the polar diagram tend to be lowered as the operating frequency is increased."

In other words, with fixed height and increasing frequency the main lobe of the elevation pattern is at a lower angle. The exact thing is true for any horizontal antenna, so there is absolutely no advantage to the extended length antenna. There are several disadvantages however.

Varney continues:

"Recent experiments by the author to determine the importance or otherwise of "unbalance" effects caused by the direct connection of a coaxial feeder to the base of the matching section had a rather surprising result. They proved that, in fact, the hf currents measured at the junction of the inner conductor or (sic) the coaxial cable with one side of the (balanced) matching section and at the junction of the outer coaxial conductor (the shield) with the other side of this section are virtually identical on all bands up to 28mhz, where a slight but inconsequential difference in these currents has been observed. There is, therefore, no need to provide an unbalanced-to-balanced device at this junction when using coaxial feeder."

Only to say later:

"Under certain conditions, either due to the inherent "unbalanced-to-balanced" effect caused by the direct connection of a coaxial feeder to the base of the (balanced) matching section, or to pick-up of energy radiated by the antenna, a current may flow on the outside of the coaxial outer conductor. This effect may be considerably reduced, or eliminated, by winding the coaxial cable feeder into a coil of 8 to 10 turns about 6in in diameter immediately below the point of connection of the coaxial cable to the base of the matching section. the turns may be taped together or secured by nylon cord."

So I guess it is a 'discussion,' with Varney arguing with himself <g>.

Hi Ben,

The 75 Ohm source will see an 124 Ohm load (nearly 2:1 SWR), but the cable will probably be a flat line (no ghosts) all the way to the video load. As long as the source is stable with this initial reflection, it should work.

If the source is not stable (observe for the loss of fine details lost in very close ghosting or the presence of ringing), try my design.

The doublet is usually a multiply of 1/4 or 1/2 wave lengths. That would be around 130 feet on 80 meters and 65 feet on 40 meters. The G5RV is not but some other length. Around 110 feet or less on 80 meters and 55 or less on 40.

Probably the result of an inductive pulse. When you think of the tower as the
primary 'winding' of a huge transformer, then that makes
every conductor that is within its influence a secondary, with the
appropriate current flowing, developing whatever voltage that Ohm's
law dictates depending on the lightning strike strength, etc..

> entrances.
>

When you consider the lightning bolt (flowing through a metal
tower or even a direct ground strike) as a transformer primary
then whatever voltage is induced into a conductor depends on
the same phsical features that are considered in the design of
a transformer. Spacing, conductor orientation, conductor length
and other things.
And considering the exremely high voltages and currents involved
in most any lightning strike, no iron core is necessary to induce some
pretty damaging currents and generate some quite high voltages in your house
wiring.
It then becomes clear that some of the 'strange'
effects of lightning strikes are not really so strange after all.

> I guess one should treat long wire runs as if they were antennas (since they
> are...).

More like transformer secondary windings.

I grew up and lived in the Ozarks and can certainly agree with his
description of the severity and level of the storms.
My closest brush with a lightning strike was in the 50's
when as a 12 year old I was talking on the wall telephone (the old
style phone where you hold the receiver to your ear and talk into
the wall mounted mike). I had just finished the call and moved the receiver
away from my ear and was moving it toward its hang-up
hook when lightning struck the phone line somewhere not far
away. Fire shot from the receiver, which I still held in my hand.
It looked like the classic jagged lightning bolt, a foot long or so.
It didn't shock me electrically at all, but sure did get my attention, and
reflexes set me back against the wall.
I never experienced the "plasma ball" lightning that rolls around on
cabinets, across the floor and out the door, but I know several
co-workers who swear they did, so your friend's experience is
certainly not unknown. On the HF Police Radiotelegraph nets, prior to 1965
where I worked, that effect most often came in from
the HF transmitting antenna which was a longer that ran from the
Collins transmitter standing behind the console in the radio room
through feed through insulator out the wall then to a point well up
on the side of the tower. A real lightning magnet!
I worked a long time around 350 foot radio towers and learned
quite a lot about the effects of lightning, and eventually how to do
a lot to prevent damage to radio gear from it. Not all of its effects
come in on the power line, many are induced onto existing wiring.

Oh- don't believe the old saw that "lightning never strikes the same
place twice". It sure does!

It's entirely possible for the currents on the two antenna legs or two conductors of an attached twinlead transmission to be equal and for there to be a common mode current on the outside of a coax line (or common mode current on the twinlead). This will always be the case, in fact, unless the two antenna or twinlead currents are exactly out of phase with each other. I don't know if Varney checked the phases of the currents, but if he didn't, he fell into a common trap of assuming that equal magnitude currents mean no common mode current.

I ran into this same situation when doing the measurements for "Baluns: What They Do and How They Do It" (ARRL Antenna Compendium, Vol. 1). More comments about the situation can be found on p. 160 of that publication.

I no longer use rope. It tended to wear out in the areas where it was constantly worked over the pulley.

I use "garage door" galvanized wire at the tensioned end to get over the "garage door" pulleys athat connect to the garage door spring. (7 foot of motion 35 pounds of tension)

At the "fixed" end I use the same wire the antenna is made from.

I used to use electric fence insulators, but last time I just used some plastic pipe as insulators.

Of course there is always a chance that one or the other of these wires is resonant on some ham frequency, but I don't lose any sleep over it. What would it do, change my already unknown pattern?

> irrelevant.

This is obvious to anyone familiar with radio technology.
Unfortunately it is not at all familiar to the general public
who must face the "new" concept of RF exposure and
it's possible effects on their health. When they see a microwave
dish or directional array they see it in the context of "another sun"
that spews it's damaging rays every which way. Most are
totally unfamiliar with the fact the energy is more restricted
than a flashlight beam. The fact that it is here, close by, that it is
even present is all too often seen as a major hazard. This is what
must be countered with education.

Corporate deception as has been in the news for the past few months
surely leads to suspicions of lying to avoid responsibility in
more ways than just stock market manipulations.

3437. Feeding Horiz. Loop without Tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-18 19:45:08 UTC
From: Harry Williams <harry.w.williams@syntegra.com>
Message-ID: <3C715A40.3A6C6814@syntegra.com>
Source record: 148325

I have a 160M horizonital loop that is fed in a corner with 450 ohm ladder line. I now have an amp and would like to use if with the loop but the tuner is rated at only 300W. Is there a way to broadband the feed to the loop so I could run RG8 or whatever out of the shack and then couple it to the 450 ohm line thru a balum that would give me an swr under say 3 to 1 over a wide frequency range? I would like to eliminate the tuner all together and have a feed system that would handle a KW.

Thanks,
Harry - W0PIY

3438. Brightness Temperature -- Radio Astronomy

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-18 19:48:55 UTC
From: Wayne Watson <mtnviews@earthlink.net>
Message-ID: <3C715AAC.F268CFA9@earthlink.net>
Source record: 148326

I'm looking at a book on radio astronomy and the author talks about calculating the equivalent
blackbody temperature of the galactic center from the formula:

Teq = (b*l*l)/(2*k)

where Teq is the equiv temp
b is the brightness of the object in watts/meter*meter/cycle per sec/steradians
l = wave length (15 m is used)
k=Boltzman constant

His answer is 50,000K. No mention is made of what b is. I would guess this is derived by some
measurement with a radio telescope.

In fact, how does one use a radio telescope to measure the required brightness? Is this *easily*
done? I take it that such brightnesses are measured over surfaces rather than points. How does one
find the (necessary) power over the surface of an object? I would think the resolution of amateur
radio telescopes would be so low as to make it very difficult to measure the brithness of an object
like Mars or Jupiter.

That, and introduce additional loss. If the wire really was resonant,
made of steel, and close, losses could be high.

No one makes a tank coil or loading coil out of steel, for good reason.

I'm not saying it would kill your attempt at DXCC, but every old timer
knows that sometimes "just another .1 db" can make all the difference.

3440. Re: Barker&Williamson Dipole-How Constructed?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-18 19:50:48 UTC
From: Patrick Croft <mai@iquest.net>
Message-ID: <3C715B18.E074390B@iquest.net>
Source record: 148328

The question was relating to the specific parts used in the B&W T2FD. Here is the basic details for the B&W which is available on the B&W website (when all else fails, read the manual - this case, the website). A Google search produced over a dozen sites that list construction details. I suggest anyone considering fabricating this type of antenna do a little reading. You'll quickly note variations of formula and mechanical methods used.

The overall antenna length is 90 feet, it's spreaders are 18", the terminating load resistance is 600 ohms, it uses a 12:1 balun and depending upon which model, either copper weld or SS wire, 14 or 12 gauge. All of the spreaders (0.5" tubing) and the enclosures for the load and balun are made from PVC pipe.

That should resolve the posters original questions.

As to the comments its a resistor on the end of coax, I suggest you read up on transmission lines and review termination effects on varying wavelengths. A excellent site to get you started in your education is Larry Cebik's, www.cebik.com. L.B. has a couple well written articles on the matter dealing with facts, not bias. A frequency sweep of the T2FD will quickly show that it is like most non resonant antennas in efficiency. That is, reduced efficiency where it is shorter than a half wave at the frequency of interest and a greater efficiency where it is longer than a half wave. No new physics here.

Bests,

Patrick

>last thing that might be trivial or just so simple that it eludes me. I say
>I'm running a 1/2 size G5RV but others describe it as a doublet.

In Varney's later article, he mentions that all of his dimensions can be halved
if you have space constraints, but at 67 feet, you're larger than 1/2 of a
102-ft. g5rv. So it's not really a 1/2 size g5rv. That length, however, is about
right for a 1/2-wave 40-meter dipole.

The g5rv is *one* type of dipole, but not all dipoles are g5rv's. A g5rv is
typically 102 feet long, fed with about 30 feet of twinlead, a choke, and coax;
or, strictly twinlead in an earlier version.

Look in the back-of-book index in your ARRL Antenna Book under "dipoles." The
g5rv is only of of may different kinds of this animal.

Uncle Peter wrote:
"I suspect most phone line devices being damaged by lightning is due to transverse voltage spikes."

That is probably right.

NEC requires telephone station grounds to be interconnected with power grounds at the customer`s premises because of shock and fire hazards.

This is also a first cut at lightning imposed equipment damage.

The telephone station protector is usually a pair of carbon or gas tube arc gaps. One for each wire. The common ground connection for these gaps is connected by a #12 or larger copper wire to the power system ground point. The phone ground wire must take the shortest and most direct path and be free of splices.

When voltage on a phone wire rises to a gap breakdown voltage level on that wire, the gap may fire. It is almost certain that both gaps won`t fire simultaneously. A common-mode surge is almost certain to be turned into a differential-mode surge at that point.

The phone set on-hook is disconnected from the line except for the bell circuit. The bell and its series capacitor can "take it".

Off-hook, there is a varistor circuit across the line in the phone instrument to control differential-mode level on the line.

On customer owned and maintained equipment, it is the customer`s responsibility to provide differential-mode protection for his equipment.

Best regards, Richard Harrison, KB5WZI

Hi Roy,
So, simply put, you're saying that current must be equal and phased
180degs to avoid current flowing onto the outer coax shield and causing RFI,
correct? With a tuner giving balanced output to window/ladder line,
currents will be equal on both sides. But, what about phase? Does it
exist/matter on ladder line? In simple terms, how is it measured (using
equipment that the common man can afford)?

I've never had too many problems with rfi from the car itself. I think the most noise I've had on HF mobile was due to tire static at high speeds. I've heard of some "dust" that can help on that, but I've never tried it. Also some say to ground your wheel bearings with a spring inside the cap. MK

Most strikes have multiple down leaders though. You might have a
strike go to ground at many places with smaller branch strikes. I've
noticed many times with fairly nearby strikes that I can hear my
antenna connectors arc from the energy that the antennas pick up.
>

Sure, it can happen, but I think a direct surge is more likely. You
can protect against these surges a good bit if you run a grounded ring
of thick wire around the house. But on the other hand, I have none of
this here, and have had strikes on my mast which is against the house,
about 5 ft from the breaker boxes, power,telco,cable tv, lead ins,
etc, and I haven't had this problem here.
I was totally unhooked from the outside world though in the shack.
Being I had no damage from a strike 15 ft from where I'm sitting, I
don't think surges from just being close do too much. I think other
things can cause more problems, such as having different ground

potentials.

Oh, I have quite a few times. IE: using the wire ring around the
house. But being I've had strikes up against the house, with no
apparent problems to nearby wiring that was 10-15 ft away, I don't
worry about it too much. I'm one to say, if it ain't broke, don't fix
it..:) I do know a few that use the wire rings around the shacks. MK

Harry, as in life, with RF there is no free lunch. Invest in a high Power ATU and use the lowest loss coax and open line you can afford. My 480 ft horizontal loop and ATR-30 give me a very frequency agile system. I typically run 500 watts and have enjoyed 160-10 meters with a single antenna.

What you describe is not a G5RV. [Louis would turn in his grave }
you are describing a 67' doublet or dipole.
The impedance at the feed point will depend on rthe length of the
ladder-line.
50' would work well but ....
a far better bet is for you to reduce the top span to 51' and run 34' of
ladder-line .
The line should not radiate.
Bryan

Is that the noise I hear when going over bumps - from the tires? I'm
hoping that the Clear Speech speaker system will filter it out.

Yes he says coax with a TUNER. Harry was wanting to avoid a new, full
power tuner. the answer to Harry's question of direct feeding without a
tuner is NO. Physics hasn't changed.

It's fairly easily done with a 100MHz dual trace scope and pickup toroids.
Short an o'scope, one can calibrate the pickup toroids, wire them in
opposition, and rectify the vector sum to get an idea of the unbalance.

Check out my All-HF-band dipole on my web page to obtain the theory behind what
you want to do. I bought an amp and didn't want to have to buy a high power
antenna tuner. In general, locate the current maximum point on your ladder-
line and feed it at that point. With any luck, you won't need a tuner.

Physics hasn't changed but maybe you don't know everything. Check out
my All-HF-Band-No-Tuner-Dipole on my web page to see if you think I
violate any laws of physics. If one is using 450 ohm ladder-line and
the 450 ohm SWR is between 4.5:1 and 18:1, the 50 ohm SWR when fed at
a current maximum point will be equal to or less than 2:1, i.e. a
near-perfect match.

Try "550" Cord. The stuff is stranded nylon inside a sheath. It is what the lines on parachutes are made from. You can usually find it on sale in places like the Outdoor Sportsman cat.
Have used the stuff years. It will eventually chafe, most anything will. But it is designed not to fray from chaffing, not good on a parachute.
Comes in camo, white and black, just in case the YL has a preference.

FWIW, my '97 Escort wagon had what must have been plastic bearings on the front wheels. Absolutely zero connection measured between the wheel and body, even when rotating the wheel. I contacted the local Ford dealer and they spent a fair amount of time researching the problem, but never found a solution. The wheel static was horrendous.

I finally sold it, but before buying the next car (Dodge Spirit) I measured the wheel-body resistance. Being essentially zero, I took it and have no wheel static at all. Did get some odd looks from the dealer, though.

Hi J.,
The far-field is *usually* defined to occur at distance 2D^2/lambda.
It has something to do with the wave differing from a plane wave by
pi/8 or something like that. Very close to the antenna is sometimes
called the near-field and sometimes called the reactive near-field.
The intermediate distance is sometimes called the near-field and
sometimes called the radiating near-field. Usually which region is
being referred to can be determined from the context or a quoted
distance, but not in this thread. When Ian sez near-field, I'm 99 and
44/100% sure he's talking about the radiating near-field. When Richard
H. sez near-field, he's talking about the reactive near-field.

I hadn't noticed that the UK and US have differing meanings for the
far field. If you've seen the UK use a distance other than 2D^2/lambda
for the far-field, please post it. That could explain a lot of the
confusion here. 73,
Bill N3WK

Yes, you could do it with two ferrite toroids and either look at both on a two-channel scope or wire the toroid outputs in series with a phase reversal. That way, what you'd see is the vector sum of the two currents. But you can also just put both conductors of a twinlead feedline or the whole cable of a coax feedline through a single core. Then you're directly measuring the common mode current. If you put a 10 turn secondary on the toroid and put 50 ohms across the secondary, the current on a wire (or total common mode current for both wires) going through the core, in amperes, is 1/5 the voltage you measure across the 50 ohm resistor, in volts.

Sorry, a EE degree and 40 years engineering experience does funny things to
an otherwise normal person. :-) Run the ladder-line through two toroids, each
with maybe a ten turn secondary. These act like transformers and yield a
voltage proportional to the current in each leg of the ladder-line. Calibrating
them means getting the same voltage out of each one for the same current
through them. Once they are calibrated, the two voltages can be wired in
opposition such that if no common-mode current exists, the output is zero
volts. Any voltage output is proportional to the common-mode current. I'll
try to put something with more detail on my web page.

Bryan:

It is an industry standard rating. Obtain a copy of the latest revision of
EIA Standard RS-222, "Structural Standards for Steel Antenna Towers and
Antenna Supporting Structures" for background and test information for
outdoor antenna structures. You will find a map of expected wind velocities
in the US, and the statistics used to develop a consensus survival standard.

3468. "Far Field (UK)" - Was: Cell Tower Effects Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-19 02:56:53 UTC
From: "J. Harvey" <JM001.Harvey@sympatico.ca>

"Bill Klocko"
> If you've seen the UK use a distance other than 2D^2/lambda
> for the far-field, please post it. That could explain a lot of the
> confusion here. 73, Bill N3WK

The "UK" definition of "Far Field" that I met in Great Malvern, UK was something like the following:

When ray tracing from a structure (like an airplane) that is illuminated by RF (like from a low directivity antenna installed on that same airplane), the "far field" is where you are sufficiently far away that you don't have to keep track of the exact distance from the structure (airplane) to the viewer (plot surface). In other words, once the "rays" leave the structure and are heading towards infinity, then the algorithm simply adds them up immediately without concern for the intervening distance (between the structure and infinity - obviously !). Once you are sufficiently far away (in the "Far Field(UK)"), this is a reasonable mathematical approach. The distances are extreme.

On the other hand, if you ask the program to calculate the "near field", then the software will ask you for the exact (!) distance of the plot surface from the origin. The antenna gain pattern at some angles may be sensitively dependent upon the exact distance. It may also be dependent upon where in (or near) the structure (airplane) the origin just happens to be. If you want the plot at 30 meters distance, then the program will take that as exactly 30 meters and will keep track of the phases of the contributing rays and add them up (accounting for exact phase of each) on the surface of a sphere exactly 30.00000 m from the origin. Basically, you only ask for the near field plot if you are trying to reproduce (explain) actual measurements that are always made in the "Near Field (UK)". Such attempts are difficult (impossible) due to the sensitive dependencies mentioned above.

These UK are not my definitions - I'm not going to defend them. Perhaps there should be some new words made up to describe these "Far Field (UK)" / "Near Field (UK)".

How about "Flugerbooten" and "Nergerbooten" ?

At various different times lots of people wrote heaps of stuff about radition hazards and ERP.

>> lotsa snippages

I'm a technician so, unlike engineers and other smart folks, I can only operate in the real world. So let's try a real world pretend (Keh?)

I have a transmitter putting out 10 watts being fed into a parabolic (dish) antenna of diameter, say, 1 metre. 1 kilometre away I have a reciever with an antenna of some kind and a meter indicating received signal level ('S' meter).

I also am fitted with an 'S' meter, it's glued to my forehead, and indicates the amount of power being absorbed by my body when I am illuminated by an electromagnetic field.

I now stand directly in front of the TX antenna. The 10 watts is distributed across the area in front of the antenna, my body is occupying some portion of this area, my 'S' meter indicates some level of power being absorbed by my body. This amount of power is proportionate to the ratio of my body area to the dish area ie some of the power is 'getting me' and some is 'getting past me'.

Now I replace the dish with one 5 metres in diameter. I know that I can't create or destroy power, I'm not putting in any more power anywhere, so there's just the same 10 watts but now distributed across a larger area. My body area is now less of a portion of the area of the dish so I find my 'S' meter reading is lower. Makes sense, more of the power is 'getting past me' so less is 'getting me'.

But at the same time I know that the 'S' meter on the remote receiver will read higher with the bigger dish. The bigger dish has a greater degree of gain over that of an isotropic antenna. The ERP is higher.

I start walking away from the dish and towards the receiver, and find a point after which my 'S' meter behaves like the other one. Hmm... so we have two regions, in which things happen different, like.

I GOT IT!! Of course, ERP stands for EFFECTIVE Radiated Power and the EFFECT is only true for the far field situation.

Giddy with the concept of actually thinking, I remove my 'S' meter - OUCH - I now take no further interest in the discussion. Even techies feel some pain. It's proportionate to the vector sum of the square of the remaining engineers...

Steve (Cess) Poole
DownUnder, LHS

PS: Personally the only issue I'd give a rats about if a mobile phone base station was installed 100 metres from my home would be the aesthetics.
But there's no way I'll ever use my mobile for more than 1 or 2 brief calls a day. I don't think the heating effect is the be-all and end-all of the story. I expect the mobile phone health issue will one day emulate the tobacco issue of today.

Everyone is beating up on Ian White, G3SEK.

A SIMPLE THOUGHT EXPERIMENT (read carefully if required):

All else being equal, if you peer into the edge of a huge (very high gain) dish, you are further away from the feed horn than you would be if you were to peer into the edge of a much smaller (very low gain) dish. Get it folks ? Bigger dish - less exposure. Okay ?

Although I don't speak for Ian, I believe that this was his 'Main Point'.

Yes, Ian's comment was slightly off the drift of the thread (at the time), but it is a counter intuitive idea isn't it. Counter intuitive concepts are precious and should be treated with a little bit more respect.

Yes, we all know that this only applies in the area adjacent to the dish (the "Nearby Field" ?). It is perhaps NOT a coincidence that this is the exact area where concerns about RF exposure might be most reasonable (in some cases). Maybe Ian is onto something here, eh ?

All this 'blah blah blah' with counter examples regarding elementary antenna gain are missing the 'Main Point'. And that, according to Martha Stewart, is a Bad Thing.

Logically yours,

J. Harvey, Ottawa

Bill Klocko wrote:
"The far-field is "ususally" defined to occur at distance 2D^2/lambda."

That`s a huge number for big dishes and small wavelengths. Death ray research may be more promising than we guessed.

I recall from looking at noise response of shielded loop antennas that one of the induction fields declines as the fifth power of the distance from the source as compared with the radiation field which declines with the second power of the distance from the source.

Suppose you were 100 wavelengths away from an antenna and you move to 200 wavelengths from the antenna. You`ve doubled your distance away. What happens to the watts per square meter?

When you double the distance away, the power per unit area in the wave is reduced by a factor of 4. That`s from double the distance squared, for the radiation field.

But the reactive volt(amps) in at least one of the inductive fields are reduced by a factor of 32. That`s the value of 2 to the fifth power (32). That is a lot of shrinkage in near-field energy and such a rapid reduction of reactive energy is consistent with FCC policy of considering the far-field to be sufficiently dominant at a distance of only 3 wavelengths for measurements in the broadcast band.

I don`t believe dish antennas are supernatural. Being powerful natural performers is good enough.

That may not be from energy that the antennas pick up from the strike.
It most probably is due to the high potential from the earth under the
charged cloud.

A common experience of this is when your hair stands on end when there
are lightning clouds in the vicinity. The charge is from the ground not
from the clouds.

J. Harvey wrote:
"Bigger dish - less exposure. Okay?"

J Harvey and the Aussie are exactly right. When you are positioned directly in front of the dish, the same power is spread more thinly on the area of the larger dish. I am grateful to Ian for pointing this out.

Another point is that in a periscope antenna system, the larger dish has lost its dis-advantage over the smaller dish in a distance less the the dish-reflector spacing at the tower. And, the tower doesn`t have to be unusually high. By the time radiation from the large dish reaches the reflector its energy makes a tighter spot than the energy from the small dish. All the gain that a dish will produce is realized at the reflector. The big dish produces the higher power density.

The point that seems ignored is that the dish is located atop a tower or tall building or some such structure where its distance to anybody who might be overexposed is enough to place them out of harm`s way. That is the argument I prevailed using with two Ohio senators, one Ohio congressman, and the FCC.

I can`t guarantee the same argument would work again because most people are dead set on believing what they want to believe regardless of the facts.

Much, much, much more common are flightline crew 'head strikes' (<KLUNK>
"Owey! Uh oh...") on the bottom mounted antennas and other protrusions.

If an airplane antenna did hit a big goose in flight (for example), it would
probably tear off the larger part of the antenna. The fuselage and doublers
should survive, but might be bent. Better the antenna than the windscreen.

If these two cables are coax, ie., unbalanced, just use a two-resistor, minimum-loss, L-matching pad. The loss will hardly be much more than the loss in a matching transformer and the operating bandwidth will be much wider.

For design of minimum-loss L-matching and other T and Pi pads, download program (guess what) MATCHPAD from website below. It will tell you the values of the two resistors and the actual minimum loss in dB.

They are both right I`d say from many years listening to and watching
arcs in broadcast antenna systems.

Charged air sweeping past would cause insulators to flash over in
advance of the storm. Guy insulatore could be heard popping and seen
when the sky was darkened by the storm or time of day.

Later when the storm was closer, lightning strikes in the area would
cause sympathetic flashes across guy or base isulators.

The power density from a bigger dish is smaller in the "near field", but it's larger in the far field. It's this crossover effect that makes the subject so slippery.

Yes, that's the crucial stage. You have done the technical assessment, but it sits there on the table, unopened, while you try to convince the people you know what you're talking about. What they are judging is actually *you* as a person - not based on your technical ability, but on your ability to explain it in ways they can understand.

Most people understand that if no-one can actually get into the hazard zone, then there's no risk. They may then understand that a high tower actually protects people at ground level.

Slightly more tricky is to explain that the greatest ground-level power density is generally where the edge of the main beam first touches the ground. I usually try to explain that in terms of holding a flashlight shining horizontally, and asking them which area on the ground is most brightly lit. Then compare that with the brightest area in the main beam.

You have to educate people about things they haven't previously thought about, so the most important thing is to keep their attention and interest so they follow along with you. Take a flashlight and show them!

>confusion here.

This is not a US/UK language difference. Since there is no sharp physical boundary between the near and far field, maybe it's to be expected that there are a number of alternative definitions, depending on the viewpoint.

I was using "near field" to identify the region along the axis of a dish (or other aperture antenna) that has a peak in power density at its far edge. That's where the E and H fields are starting to get their phase together. The near-side rising edge of the peak is formed by increasing phase convergence; the far-side falling edge is formed by the inverse square law taking over as we move out into the far field.

The distance of the peak is approximately 0.2D^2/lambda (that's zero point 2, not 2 as Bill wrote). With large apertures and small wavelengths this distance can become surprisingly great. At about twice that distance the power density is within a few percent of what we'd have predicted from a far-field inverse-square calculation, treating the antenna as a distant point source. But the peak is definitely a near-field effect because an inverse-square calculation doesn't predict any peak at all.

That leads us towards some kind of "definition-by-veto". There are several different viewpoints on what constitutes "near field": reactive near field, radiating near field, close-enough to a plane wave, close-enough E and H phase convergence, the radhaz approach outlined above, and so on... If any one of those viewpoints says "Hold it - I'm not in the far field yet", then they must still be in the near field!

I'm not taking sides either way, but a GOOD company will respond to
customer issues regardless of the customer's "attitude". If Cushcraft
is ignoring Mr. Baron because of his supposed "attitude", they are
making a serious mistake.

So the question is, are they?

I did NOT take this attitude. Also, there is no way they can tell an attitude when calling on the phone which was never answered. They had an answer machine that you put a message on and they never called back.

I am suer it is because I have had to order parts before and they are just going to stonewall any problems with the antenna or lack o parts support which is by far the worst I have ever seen.

3487. Antron A99 vertical vs RS look alike

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-19 12:45:27 UTC
From: rons533@dejazzd.com
Message-ID: <3C72485C.6E80@dejazzd.com>
Source record: 148273

After doing research at eHam.net for many reasons I decided to purchase an Antron/Solarcon A-99 vertical antenna to use on 10, 12, 15 meters. I learned that Radio Shack used to sell the "same" antenna under their name years back. After calling several RS stores I located the antenna and since they no longer carried it they discounted the price. Guess what,, I can't get the antenna to tune better than 4:1 without a tuner anywhere. My question I guess is. Is this really the same antenna as the Antron/Solarcon? Is anyone using the RS without problems?

Thanks

I replied to this from home, but don't see my answer here, so I'll do
it again [am at work now].

Lets look closer at the formula....

b = watts/(meter*meter)/Hz

and...
Hz is the bandwidth of your receiver.

watts/(meter*meter) is the signal strength in watts per square meter.

If you know what your antenna and receive gain is, you can calculate b
from the measured output of the receiver.

Multiply b times the wavelength squared and you get watts. There is
another formula, P=kTB. P is power in watts, k is Boltzman's constant
= 1.380622e-23, and B is the bandwidth. I don't know where the 2
comes from, as I don't have any of my references with me. The power

received by a radio telescope is quite small, and it is more conventient to use temperature.

What you are measuring with a radio telescope is the average signal strength that is inside the antenna beam, not the surface of the source.

Again, I don't have my books with me. They are at home, so I can't give any more details. This is all I can recall from memory.

What book are you reading? Kraus's? I worked at the Ohio State radio telescope when I was getting my Master's degree. Unfortunately, I have an aversion to starving, and am no longer working as a radio astronomer. There aren't enough jobs to go around.

You are correct, there are very high priced professional packages that do just exactly what you want.

As to a reasonably priced consumer package - Topo USA Version 2 (or higher?) from DeLorme will allow you to select 2 points and show a side view or profile view. You can definitely see line of sight from this.

That may or may not help you accomplish what you want, but it's the closest thing I've found short of professional propagation software. Professional software takes in to account the specific frequency, power, antenna design, etc. You have to do all that in your head with anything short of that.

Carl.

3490. Re: Feeding Horiz. Loop without Tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-19 13:33:27 UTC
From: Alan White <alannc44@ix.netcom.com>
Message-ID: <Husc8.15806$rs6.7919687@typhoon.southeast.rr.com>
Source record: 148279

In the beginning he describes the use of a loop cut for 160 meters which he uses for higher frequencies with the aid of a tuner. His ninth paragraph:

"Directly feeding the loop antenna is obviously the simplest, however, you be your own judge and feel free to try it both ways. All 3 of my loops are directly fed with 50 ohm co-ax. My 17 and 10 meter loops are both vertically suspended and are relatively in the clear but low to the ground."

I used to use a full wave loop for 20 meters with a quarter wave section of 75 ohm coax and had an easy go at it. While this was suspended vertically, I did have a reflector. In otherwords, a quad. My understanding is that the impedance drops when you locate a reflector behind the driven element. Right now, I have a 40 meter full wave parallel to the ground at about 30 feet high stretched around the yard. My SWR is not flat across the band, but it does drop to 2:1 for at least 20 khz. Perhaps the ground acts as a reflector and lowers the impedance?

Hi Everyone,
I have a triangular tower and I want to mount the rotator inside the tower to take the strain off it. I have been told I will need to put some bearings in the tower to support the weight of the aerials and help with the "side to side" support, but don't really know how this is done. Anyone have any suggestions/Webster/pics that might help. I would also like to add a break as well and was thinking of using an old boot opening solenoid to achieve this, again any ideas on this would be great.

And if you're not into "investing" in an ATU, a cheap,
homebrew, L-network can be had on a piece of plywood.
The coil would be wound of #6 copper ground wire wrapped
around a hunk of 6" ABS sewer pipe and tapped with a sturdy
clip lead. The capacitor would be an assortment of surplus
doorknob types, selected with a clip lead. If you want
a finer adjuctment on Xc, place a tappable inductor in
series with a small-valued capacitor (high Xc) and adjust
the inductor to "subtract" its reactance from that of
the capacitor to get exactly the right value. Not very
"frequency-agile", but my guess is you could map enough
inductor taps and capacitance values to get a decent
match over the 160-meter band.

The 75 Ohm cable will be coax and the 100/120 Ohm cable will be CAT5
(balanced) although I'm not opposed to running the CAT5 unbalanced if
there won't be any more signal degregation than a coax run. I want to
take advantage of the inexpensiveness and multiple conductors in the
CAT5, any anti-interferance measures is just a bonus. It'll be run
probably under 500 ft anyway.

Mr. Moore,

I've yet to notice anyone claiming total knowledge on this thread and
I'm sure I don't know everything. Your use of varoius impedance feed
points with knife switches has been well advertised by yourself on this
newsgroup and others. Certainly it offers a method of feeding in some
situations. It doesn't however broadband the antenna as Harry was
asking about; "Is there a way to broadband". It simply offers multiple
tap points to allow improved coupling at specific frequencies. This is
nothing new either, and certainly not a method of broadbanding an
antenna.

Bests,

Patrick

Thanks,
Harry - W0PIY

I had a terrible time with them about my R7000 also. They had a bad product and didn't know what to do with it. I was offering to PAY for a replacement trap and couldn't get anyone's attention for weeks. It took a call from my local HRO manager to get a response.

I have heard lots of these stories. Cushcraft needs to get their act together. I sure don't want to deal with them again.

> radio.

Not if the feedline radiation is actually occurring *at* the house
and thus radiating into the housewiring where it can easily find its
way inside a poorly protected TV causing overload.
I discourage any system that allows RF from the antenna to find its way back
inside the house.
In my own situation, at one time I had an 80 meter dipole running over the
roof of the house. Anytime I ran over 50 watts or so, I
experienced RFI of various sorts, to the extent of even having the
hallway light (resistive) flicker on and off when I ran the amp.
I moved all my antennas well away from the house, and have
since had no RFI problems whatever. It's too bad that many hams
aren't able to move their antennas far enough away from the house
to get that effect.

>From this and your follow up post I guess that this wire will be only
a few >feet above ground.

Yes. Probably a "V" w/ 30-35' center, although a semi-flat top at
20-30' might be an alternative.

> I suggest that you consider a trap dipole for your three bands. Forget the
> ladderline since it is such a small part of the overall transmission line and >is way
more trouble than it's worth.

The reason the ladderline (as part of a G5RV) was attractive was that
it gave me a connection point close to the ground, since I will have
to roll out my coax to it when I want to use it. I suppose running
coax to a grounding block, or other type of coupling would serve the
same purpose.

>Traps built from coax are easily made; if you
> are interested, I can provide references.

I have looked over some of the materials at ARRL's website. If you
have other references, I would greatly appreciate your sharing them
with me.

> Use a balun at the feedpoint (ferrite if you can afford it, otherwise, a few
> turns of coax) and run the coax to the rig.

Coax would get the nod here; not only cheaper, but it would match the
traps:).

>I know you've shelled out for the tuner in anticipation of needing it
for a >multiband antenna but it will still come in handy for covering
the extreme >band edges, particularly 80 meters.

That is okay. The less the tuner has to do, the better. (If I ever get
a suitable spot to try Cecil's creation, the tuner will live in the
Jeep, anyway :)

> Welcome to the fold.

Thanks. Too bad my Elmer wasn't around to get me off my duff 25 years
ago (when time and money both seemed more abundant)! If there's a wall
of shame for those who procrastinate getting their ticket, I reckon I
ought to be on it.

I have one that I regularly use on 10 M. Have had it up for about 4 years.
While you can force feed it on 12 and 17, I don't.

As for your matching problem.
When I brought the antenna home, I had the same problem. Went back to radio
shack and had them pull another one from stock. It worked fine. The
matching section inside the first one was deffective.

As I recall, it should show DC ground on the center pin, and the one I
originally had did not.

They put a little X on the deffective one and claimed they would return it.
I think I recently saw it for sale at the "back room cleaning sale". (hope
you did not buy it In CL Illinois)

Hi,

Is there a way to build a simple antenna to provide cellural(GSM
900,1800) connectivity from open ground to a basement that now lacks
of it without the use of amplifier ?
Actually the status now is that in a basement the cellural phones have
no signal and I was wondering if there is something like a
back-to-back antenna, that I could use to "transfer" the signal to
this basement.
Maybe this is a simple task but does anybody know where should I look?
(links, books?)

TIA

3511. Ladder line and baluns

I have been running an inverted L antenna. It is 51 feet on each leg (old G5RV stock) and top fed with about 135 feet of ladder line. I can tune 160-10 meters with my antenna tuner using the internal 4:1 balun. This antenna works very well and you can read more about it on Mr. Cebik's excellent site.

But, it was touchy on the lower bands and a little rough on 30 so on a lark, I tried running coax from the tuner to a RadioWorks 1:1 current balun then to the ladder line instead of using the tuner's internal 4:1 balun. WOW! The antenna tunes like a dream on all bands now with FLAT SWR possible everywhere. In addition, the tuning is not as critical and I don't have to re-tune every time I move around the band.

The antenna models with a pretty low impeadance. I guess the 4:1 balun was making the match even worse at the rig? Why are 4:1 voltage baluns fairly standard in antenna tuners? Any of you experts care to comment?

A current maximum point is a good place to feed a non-resonant antenna
system. The resistance is relatively low at a current maximum point.
A 4:1 balun can do more harm than good. They are designed to feed
200 ohm loads and work well on full-wave loops and folded dipoles.

It will work fine... in fact it's an excellent antenna for short haul.
DX performance will be less than optimum... but DX on 80 has often a
fairly high arrival angle. It would work better at 80 ft of course...
but life is full of compromises!!!

Relax... it's that way because most Americans want it that way... leaves
some of the band relatively open for DX and such. For example, if the
opened up another 50KHz to US use on 20M, it would instantly fill up,
and you would be back where you started.

Source record: 148306

There has always been a bit of disagreement on the definition of 'Far Field'.

There are two of them that I prefer.

1) The distance at which there is no longer any signficant reactive component of the field. That is, the field has completely 'escaped' from the antenna and no longer collapses back into it every cycle. In the near field, some of the energy is 'stored' in the antenna and the field is defined as being reactive (like a capacitor or inductor stores energy). If there is no loss, none of the energy is lost, just 'recycled'. If you look at the typical equations for near field, you will find that there is an imaginary term.

2) The distance at which the two field components (electric and magnetic) are orthogonal with the direction of propagation. In the near field they will not be mutually at 90 degrees to each other.

For both of these, the more gain the antenna has, the larger the near field distance. I would think that, for the program you mention, that if you ask for near field and give it a distance that is too far you may get invalid results.

Both of these are still subjective, however, because you now have to decide the value of 'close enough' for the two conditions.

I have my guess.

In most cases if the wind was above 80 MPH you would be worrying about
other things besides your antenna, like your house.

Yep, the radiating near-field can extend out to large distances. The 2D^2/lambda
expression is pretty much standard, although sometimes you have to dig to find it in texts or references.

> I don`t believe dish antennas are supernatural. Being powerful natural
> performers is good enough.

Well, there's nothing supernatural about it. Especially when the effective gain in the near-field is reduced from the far-field value.

That's what I'm familiar with - I'm glad we're talking the same
language.

> The distance of the peak is approximately 0.2D^2/lambda (that's zero
> point 2, not 2 as Bill wrote). With large apertures and small
> wavelengths this distance can become surprisingly great.

Now we're talking 2 different things here. The usual definition for
the edge of the near-field region is 2D^2/lambda. As the distance
decreases from 2D^2/lambda, the power density is less than what it
would be if it was computed using the antenna's far-field gain. In
effect, the gain of the antenna is reduced. At some distance the power
density peaks, just like you say. Your distance at which this occurs
is 0.2D^2/lambda, or one-tenth of the distance to the boundary of the
far-field region. That's probably a pretty good approximation for a
circular aperture, uniform distribution, etc., etc.

> At about twice
> that distance the power density is within a few percent of what we'd
> have predicted from a far-field inverse-square calculation, treating the
> antenna as a distant point source. But the peak is definitely a
> near-field effect because an inverse-square calculation doesn't predict
> any peak at all.

I'd agree. 2D^2/lambda seems to be a very strict definition. If you're
interested only in the distance at which the near-field gain
approximately equals the far-field gain, the distance can be relaxed.
0.4D^2/lambda is also probably a pretty good approximation. 73,
Bill N3WK

Of course there is reactive field, near field, and far field.

> I would think that, for the program you mention,
> that if you ask for near field and give it a distance
> that is too far you may get invalid results.

Since the pattern may be sensitively dependent upon relative phase from
contributing rays, the results may be different (though perhaps not
invalid - depending on the application) in certain directions with movements
of a small fraction of a wavelength.

Okeydoke [not sure if a ham can say that but I'll throw out a line].
Originally, what I had planned was the doublet but didn't really find too much *specific* construction details on it and kept looking at the G5RV thinking, "That's what was described". Construction for either is simple and straightforward enough for any ham. My conundrum began as antenna/feedline lengths didn't quite make sense. Hence, my misunderstanding and post. I did ask what the difference was between the two and, after becoming much more familiar with the G5RV (thanks gents), understand where the good Mr. Varney was going with his design... God rest his soul.
Either way particular bands have to be tuned through a match. If the 67' doublet top will give me operation down to 40m and the only question is feedline length, why not the 67' inverted V with a 34', 450Ohm windowline (which would make an ideal length in geographic terms? Would going with a 51' inverted V work down to 40 without shorting it as a T? What would be the benefit/tradeoff of the 1/2 size G5RV? What would be benefit/tradeoff of the doublet?
I do know this, the feed line length of the G5RV is stated and I don't know how to calculate a good feed line length for the doublet. In the middle, I've picked up a lot of good practical knowledge for both. Thanks.
Best Regards,
Drink

Is this a question? If so, are you talking HF, VHF, or UHF here?
I've enjoyed using the tubing from the "Toy & Model" chain for
various UHF projects. It is cheap, and is available in aluminum
or brass.

About 80% of the time when I hear of or see noise issues, it involves Ford vehicles. I don't know why, but it just seems that way. It was that way back in the 60s when I first started put-
ting radios in cars. We used to be sitting at home listening to the AM radio (FM was just com-
ing into vogue) when ignition noise would appear and rise in crescendo. One of us would remark, "There goes a Ford", and sho' nuff, you could look out the window and there'd be a
Ford driving by! No kidding! <<g>> Now, I know there's bound to be diehard Ford fans
reading this, but I went away from Ford in the early 70's not only because of the noise problems, but on account of reliability issues as well. Ford gave me strong legs and a spelling
lesson--all in one; I learned to spell F O R D backwards. Driver Returning On Foot! LMAO!
To this day, I refuse to own a Ford and opt, instead, to buy vehicles that always "dress for dinner"; they always have a "bowtie" on! And the only "noise" I hear is the sound of the radio!

I have a friend who does alot of driving around town. He sees alot of unused CB antennas in various states of dis-repair on rooftops in his travels. You would be surprised with how many homeowners are happy to give their old CB antennas to a guy who offers to take it down safely for them. He has developed such a surplus of various tubing sizes that he has given me and a few other friends large supplies of aluminum tubing to work with. I'm not sure of his exact approach but whatever it is, it sure works!

3537. Effect of inductive resistors in dummy load?

Newsgroup: rec.radio.amateur.antenna

I need to cobble up a dummy load for some quick xmitter tests. The only resistors I have are 10 ohm 20 watt wire wound resistors which I can connect in series to yield 50 ohms.

What would be the effect of the inductance of these resistors on a measurement of swr, and is there some way to compensate for it?

Any suggestions would be appreciated.

Hi Drink,

Click URL below to download program DIPOLE2 for any dipole, any height, any balanced pair feedline Zo, length, velocity, any balun, any coax feedline Zo, length, velocity, and any L-tuner. But, as the program will show, a long length of coax rapidly decreases overall efficiency on a mult-band antenna system at the higher frequencies. Keep it as short as possible or you may have peculiar values of L-network components or L-network loss.

If you are that way inclined, you can use coax all the way from from Tx to antenna just by setting the length of twin-line to zero. Or vice-versa.

DIPOLE2, to cater for any type of feedline, asks the user to enter all wire diameters. The program needs wire diameters to compute transmission loss on the line and take SWR into account. For example, the user is more likely to know the approximate value of coax inner conductor diameter than the resulting dB. If you know the dB per 100 feet then vary wire diameter until the calculated dB/100 feet equals what you have in mind. Same applies to ladder line, or open wire line, or antenna wire diameter. But wire diameter is a non-critical dimension. A sensible guess is usually good enough.

The majority of users will use metric measurement units. It may be useful to know dB per 100 feet is as near to dB per 30 metres as dammit is to swearing.

Hit one key for a G5RV already set up for the user to experiment with modifications to see what happens to performance. Most likely you will improve it.

But see CAM, W5DXP, http://www.qsl.net/w5dxp for how to replace a tuner with a variable-length 450-ohm ladderline. Flimsy 300-ohm line is not recommended.

I tried the same thing once. You can tune out the inductive reactance
with a variable capacitor in series, but in my case, the voltage
developed across the capacitor was very high - too high to run more than
just a few watts with the capacitor I had.

The more inductance in the resistors, the less capacitance required.
The less capacitance, the more reactance, and for a given power level,
the more voltage developed across that reactance.

Somewhat counter-intuitive, but true. Go ahead and try it anyway. It's
not too often one has a chance to observe something like this.

Yes, back to back antennas work - sometimes. Use a high gain antenna
pointed at the cell site and and either an omnidirectional or a
panel antenna in the basement.

> Maybe this is a simple task but does anybody know where should I look?
> (links, books?)

Whether it will work or not depends on the signal strength available at
the roof, the antenna gains and the losses in your coax, arrester,
connectors etc.

I have used the technique a couple of times. Don't expect miracles.

> "Near Field (UK)".

What you describe doesn't sound that much different than the question
in the other thread. If the far-field pattern of the cell base antenna
is to be computed, all the rays from the antenna are basically
parallel and the contributions are added up. For a near-field pattern,
the vector sum of the rays is computed.

If the algorithm is well done, a near-field pattern computed at a
far-field distance *should* be pretty much like the far-field pattern
computed at the same far-field distance. OTOH, a far-field pattern
computed at a near-field distance should be nothing like the
near-field pattern computed at the same near-field distance.

> How about "Flugerbooten" and "Nergerbooten" ?

Nah. Makes it too simple. 73,

You have not considered the additional feedline loss from the coax
when it is not matched nor the loss in radiation efficiency due to the
finite Q traps acting as resistors at resonance. But really the
simple way out especially if you're temporary, is to put up a piece of
#16 copper wire as long and high as you can get it and feed it exactly
in the center with low loss open wire transmission line of length
determined by the location, even 300 ohm TV twin lead. You really
don't need a balun but you do need a tuner. (If you're a normal ham
you always will need something to tune, to make you believe you're
optimizing something.) Quick, simple, light, and satisfying-- believe
me, I've done it since 1957.

"CAM" mentioned:
> I have put the horizontal and vertical radiation patterns
> for my 130 ft All-HF-Band antenna on my web page...

I was all excited there for a minute. I thought that I might have some material to enter into MS Excel to double check your patterns (make sure the overall average gain hasn't wandered up past 0.0 dBi) and to estimate the overall efficiency. Then I realized that these plots were *predicted* radiation patterns from EZNEC and not measurements. Oh well - saves me a couple of hours work...

3547. Re: Antenna Wind Survival

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-20 04:04:38 UTC
From: "J. McLaughlin" <JCM@Power-Net.Net>
Message-ID: <u7681a5i425k0f@corp.supernews.com>
Source record: 148234

Use care in using wind survival ratings. The standard contains a factor to account for gusts. (this is good) Some manufacturers use no such factor.(this gives you a number that is unrealistically too high - bad) In other words, the peak pressure, which is approximately proportional to the square of the wind velocity, that an antenna element can withstand without permanent deformation is the number you want, but will not get. At least one good antenna that is for sale has elements that all will bend at about the same pressure (good design), however the wind velocity stated corresponds to the theoretical pressure of a smooth flow of air. Without ice, it will hold together 'till about 55 mph (as measured by the weather people), but will be long gone before reaching the specified 80 mph.
Survival specifications of yagi/LPA type antennas should be given in terms of pressure to cause deformation of the most weak part when the wind is head on and again when normal to the boom. (It would also be nice to have the same pair of numbers when the elements are encased in 0.5 inches of ice and to have the effective area in both directions) One could then apply a safety factor appropriate to the material and to the gustiness of the wind. The SF should also have a height factor and a roughness factor. (Flat, rural, treeless land has quite a different wind characteristic than that of a residential tract.) It is a pain to have to calculate these numbers in order to know when an antenna is likely to fail and in order to know the force loads on the supporting tower.
So.... ask what equation is used to relate the specified wind velocity to pressure.

Dear Pat:

Even reading Larry Cebik's articles, my statement is still stands. The B&W dipole is simply a very
ineffective antenna. This is the collective experience of many hams. I would refer you to eHam for the
ratings of and experiences with the antenna. For the average ham, this is a better place to start when
trying to make some initial and relative comparisons of antenna effectiveness . . . bias' nothwithstanding.

Hi All!

Irv just made it clear that his experience with the antenna was "down from other antennas" which is
what I would call poor, but for what I must assume are sentimental reasons, he thinks it is a good
antenna. So, for those of you who want an antenna that is "down a bit," here's your chance to get an
under performer. Just tell them Irv sent you!

For those hams who are interested in relative performance, I would suggest you check eHam (http://www.eham.com/) for a review of this antenna by your contemporaries. You will see that it doesn't
do very well with most hams that have purchased it. It is rated 3 out of 5 (5 being very good) and to
quote one ham, it is a "high priced dummy load."

Are they not an integral part of the deed, clauses written into
the title to the land which restrict the use of the land? There doesn't
have to be a HOA involved, although sometimes there is.

Dick:

Moving the antennas away from the house is not quite the same thing as curing TVI by eliminating feedline radiation, but you are correct--getting the radiation as far away from sensitive devices is always recommended.

I've seen wheel bearing grease that looked like it had graphite
powder in it, tho I'm not certain it did.

Check the yellow pages for "metal products". Every city has some, and they
sell tubing among other useful metal things.

They are often not in the deed itself, but are referenced as a separate
document.

If there is not any body to enforce CC&Rs - you will not find any
city or county enforcing them.

What you want is a "thrust bearing" at the top of the tower. This can
be as simple as a sleeve inside which the antenna mast rotates, but better
is an actual bearing. Best is a bearing that clamps to the mast itself, so
the bearing can take the weight of the mast and antennas - instead of the
rotator having to do so.

When we owned a fleet of big rigs each one equipped with commercial HF,
tyre static in dry weather was a problem, we cured it with putting graphite
powder in the outer bearing assembly, and dusting the inner of the inner
tyre with graphite powder.. 20 plus over noise was reduced to a very
acceptable noise level.

Hi!

Does anyone have any in-depth documentation for the Yaesu Atas-100
antenna (meaning schematics, service manual or similar, accessories), or
pointers to such?
I've searched the net but found very few references, most of which are
reviews. Only wa8lmf has something to homebrew a DC-coupler. Yaesu site
itself has nothing on this antenna.

Thanks to whoever may help me.

Looks good to me - only a few days ago I was having to defend
0.2D^2/lambda as being in the near field at all!

What it does mark is "the beginning of the end," the point where the
power density peaks before it drops off to converge with the far-field
value. As you say, 0.4D^2/lambda may be OK for some applications, but
2D^2/lambda is widely used as the minimum acceptable length of an
antenna range for accurate gain measurement.

Yes it was :)

Vhf/Uhf mostly, I use wire antennas or my A3 for HF work :)

I like to build different 2m and 70cm antennas just to see how they work
and if they are decent. Usually give them to friends who need beams.

Built several 3 ele 2 meter beams on PVC with Aluminium rod, using a
split driven elem for feed. Cant find the rod anymore.

Toy and Model chain huh, well Ill ahve to go find some of that.

Check your local sporting goods store for aluminum arrow shafts: Very sturdy, about 1/4 - 3/8" diameter. I just picked up several on sale for $2 each. Good luck on your experiments & pls keep us posted on how they turn out.

Marty wrote:
"What would be the effect of the inductance of these resistors on a measurement of swr, and is there some way to compensate for it?"

Besides tuning out unwanted inductance, there is another problem to be taken into account. A wirewound resistor of 10 ohms at d-c has more than 10 ohms resisance at r-f de to skin effect.

Skin depth penetration in resistance wire at r-f is inversely proportional to the square root of the frequency. So, the higher the frequency, the higher the resistance. The r-f resistance of a wire-wound dummy load resistance will be higher for VHF than for HF.

For copper, penetration depth is 0.0026 inch at 1 MHz. Penetration depth is proportional to the square root of resistivity. So, r-f current will run deeper in resistance wire than in copper.

Find some real non-inductive resistors for your dummy load.

Best regards, Richard Harrison, KB5WZI

Hi Richard:

That's one point many people don't understand. Many people assume that at high frequencies you don't need to be physically far away from the antenna to be in the far-field because the wavelength is small. At HF through UHF frequencies, you can be relatively close to the antenna in terms of wavelengths because the antennas are not usually large wrt the wavelength and the far-field develops at a physically closer distance. Typically, 50 - 200 feet is a reasonable distance to measure the far-field patterns for many of these antennas.

Dishes are another issue. They are usually large wrt the wavelength and the far-field develops at a farther distance. This is true of all higher gain antennas. We (former employer) used to measure far-field patterns on large dishes on a 4000 ft range and sometimes that was not long enough if the dish was really large. In that case, we had to probe the near-field and translate that into a far-field pattern.

Before circular became in vogue, some stations did use a bit of vertical
polarization but at a considerably lower ERP...presumably for better
saturation of the nearby rabbit ear market. I imagine there may be a
few remaining ones..."almost never" is accurate and even if it were
encountered it would probably be considerably weaker.

I am amazed at hams who don't put two and two together. What do resistors do?
Dissipate power. What is the purpose of the T2FD resistor? To dissipate power.
Why does the resistor need to be able to dissipate half the transmitted power?
Because, on some frequencies, the resistor dissipates half the transmitted
power. That resistor costs money. They would not put it in the antenna if
it wasn't doing exactly what resistors do.

That's 31' of ladder-line in addition to the 80' of ladder-line
that goes to the antenna. The 0-31' Ladder-Line Length Selector
allows one to fine the current maximum point (the sweet spot) on
the transmission line.

Bryan, KA9KHD wrote:
"I noticed that most antenna brands list wind survival rating of 80 mph and wonder why they pick that number?"

They need a standard for comparison. Winds exceeding 80 mph are uncommon. The pounds per square inch produced by 80 mph depend on surface shape and orientation.

Crazy George gave you a good answer by referring you to RS-222. Towers are often built for higher wind velocities than 80 mph for areas subject to higher winds.

3586. Mast grounded-help with coax

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-20 17:21:31 UTC
From: gchsbrown@HOTMAIL.COM
Message-ID: <484583c6.0202200921.5a0fe1bf@posting.google.com>
Source record: 148171

Hi,
I am concerned about protecting my house against a lightening strike to my crossbow antenna. I have the antenna on a 10 ft mast with a clamp at the bottom from which I run copper wire #8 to an 8ft 1/2 in ground rod. The rod is buried beneath the antenna so a direct strike has a nice straight chase to ground(bout 25ft).

My base(second floor of house), service panel ground rod, and antenna are all on the East side of the house. The service ground is about 17 ft from my antenna ground. My base is about 12 feet from the antenna ground and on the second floor.

Questions:
1) How do I ground my coax? If the lightning strikes the antenna, couldn't it run into my house via the coax?
2) Can I bury the coax in the ground beneath the base before I run it into the house for protection?
3) Should I connect the service ground and antenna ground?
4)Is another ground rod advisable?

If I should ground the coax, could someone give me details such as how to ground it and with what type of hardware.

Since my base isn't worth much, my first two priorities are to reasonably protect my dwelling and the second is to not break the bank.

Help and suggestions are appreciated.
PS- Im still confused after reading the tech polyphaser material.

> http://www.qsl.net/aa1ll

Paul,

The reason for using coax is that the line will be laying on the
ground when in use, and will be directly contacting metal when
entering the house. Am I correct that this would preclude the use of
twin-lead?

BTW- Nice website!

Thanks,

Allen

I`ve found the "conventional figures" used by some antenna manufacturers
for "normal" antenna installations:
60 mph---11 lbs/sq ft of antenna
70 mph---15 lbs/sq ft
80 mph---20 lbs/sq ft
90 mph---25 lbs/sq ft
100 mph--30 lbs/sq ft

Antenna manufacturers should give the effective area of their antennas
for windloading calculations and estimates.

Could it be aimed in the wrong directions? I used a dipole cut for 40m
on 40 & 80 last field day. It was up only 30 feet, drooping to 10 but
worked OK as far away as the other (West) coast albiet no DX. To my
chagrin it went deaf when I installed it at home. Turned out the lobes
were pointing at the Yukon and So. Central Africa! Not many Hams either
place. Naturally YMMV.

Source record: 148177

My antennas tend to be under 10 sq feet.
Rotors can take downward forces over 150 pounds for even the cheap rotor,
what you want to control is the side force. In the case of my rotors the
allowable antenna size is doubled by putting the rotator inside the tower.

I have used two types of sleeves in the last 25 years.

1, I use standard electrical conduit as a mast. It is lighter than water
pipe but
seems to be just as strong. Nowhere near as strong as a real antenna mast
though.

when I had "flat top" towers, I bought a coupling, made to join two pieces
of the conduit together and filed the rib out of the middle so the mast
could pass through. I mounted the coupling in the top of the tower.

I greased this point, and used car axel boots, or rubber plumbing adapters
to create an umbrella to keep the water out of the bearing.

Currently I have a "pointy top" tower, with a plain sleeve that is around
1.9" ID. My 1.75" mast just runs through the sleeve, (as the prior owner
of this tower did for 30 years). I kept the umbrella arrangement.

Having a little slop in the mast to tower bearing point, makes the alignment
of the rotator and the tower much less critical.

Rick,

In Spokane try Alcobra located off Francis Ave. in Hillyard. They have a good selection of tubing of various sizes and don't require a minimum purchase. Pacific Metals on Dollar Rd. (not Pacific Hide and Fur which 'sometimes' has tubing) also carries tubing and solid rod of various sizes. You might be able to talk them into a less than minimium purchase.

Twin-lead needs to be kept at least a couple of diameters away from
anything conductive. If you are unlucky enough to have a voltage
maximum located at a window's metal flashing, you may indeed see
flashing.

You sould try to ground it right before it enters the structure.

> 2) Can I bury the coax in the ground beneath the base before I run it into
> the house for protection?

Yep. But, you still should ground the coax.

> 3) Should I connect the service ground and antenna ground?

NEC advises all ground rods to be tied together. Use at lest a #4 solid
copper.

> 4)Is another ground rod advisable?

Not if you can ground you coax to one of the other ground rods.

For more info. Check out the ARRL Handbook on grounding.

Hi Jerry,

On review of both the source and sink of this dissipative transmission
I find:
X-Newsreader: Microsoft Outlook Express 5.00.2615.200
X-MIMEOLE: Produced By Microsoft MimeOLE V5.00.2615.200
In other words - NO SURPRISE!

Outlook Express is the world's worst vector of infection today. A
regular Typhoid Mary of the Internet.

If you must use it (both of you), learn to disable the "features" that
the "agents of evil" so admire about Microsoft products. This is the
Microsoft commitment to security through autopsy.

If you think your problem was annoying, just hand over your credit
card and financials' data to their Passport. You can't read the
source code for Windows because Microsoft is secure only to their
proprietary data, yours is another matter. Identity theft is the
hallmark of this problem beyond canceling your credit cards weeks
after your numbers were made publicly available. Yes publicly.
Hackers had only to browse to find them. Microsoft immediately blamed
a system admin - not the problem of software. Never is, hence the
continued exposure. Unfortunately they never designed the software
with so simple a source of risk in mind (the human component is ALWAYS
the source of security breach).

News headline today has yet another suit being brought against
Microsoft from BE Corp. for $2*10^9. EVERY week similar headlines
bring warning....

3598. Help with TS-440 no RX problem

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-20 19:31:28 UTC
From: krish <vu2vku@aol.com>
Message-ID: <3C73F990.837982F8@aol.com>
Source record: 148184

Hi,
I have a TS-440 which was perfectly working until i messed with it.
I bought a 7 pin DIN connector from Radio shack.
I soldered a couple of wires to pin 2 and 4.
I soldered a couple of wires for the ALC and ground.
To the end of the wires, i soldered 2 phono plugs.

The 440 instruction manual instructs one to plug the jumper to
enable the auxillary relay to key an amp.

All i did was, set the jumper and then plugged in the 7pin connector,
powered up,
put the radio in CW and keyed to a dummy.

The radio clicked and all was fine and i saw no voltages on the relay
key line. After doing this a few times, the radio seems to be
stuck in the transmit mode. NO AMP was involved.

The "ON AIR" led is lit when i power the rig on. There is no audio from
the receiver since it is cut off.

If i transmit either SSB or CW, there is no relay click and the rig puts

out full power.

I reset the processor and found that the amp keying relay is
in transmit mode all the time as soon as i power the rig.

So i am wondering if someone could help me locate the component ,
probably
in the IF or Control module , that is responsible for switching the
radio from
the RX to TX modes. It could be an open transistor ????

My guess is that it simply cannot be the relay .Its gotta be the
control signal,
putting the rig in the xmit mode, the "ON AIR" led is also on.

I have done a processor reset. Not murphys playing around. What am i
missing
in short of selling the rig, sending it to kenwood ????

I will have a service manual on hand by the end of this week.

I appreciate any tips.
thanks

I may have been given a pleasant surprise. Perhaps Cushcraft was busy,
perhaps the voice mail system was not working correctly? I do not
know.
Today I got an Email from the President of Cushcraft. He asked what my
problem was and then he had a technician call me. The result is that

they are sending me everything above Trap CT1 and it is the new model. This is very likely to correct my problems and of course it will make me a very happy camper and force a compete reevaluation of my opinions of Cushcraft. I will let you know how it turns out.

It may have taken a long time but perhaps it was an unavoidable set of conditions. In any case I thank them for the effort shown today.

Hi all:

Well I guess I was surprised too. But I find it easy to work most DX. I've even worked Australia, which is as far away as one can get from my QTH. I run about 700 watts PEP out and I often get 20 over S-9 reports out of europe. I do have a fairly quite location as my noise runs about S-6 to 7. Have you looked in the right place for the DX. The DX window is 3.790 to 3.8MHz. These days I'm seeing 2 to 3 DX stations each night.
As to pointing in the right direction, a dipole at 30' has a pattern that is almost circular. My wire runs almost east/west and if it had a "dipole" pattern it would be aimed at europe, but I hear south america very well. So go figure, it works better than it should and I'm enjoying 80m DX, and now its 43 countries.

Vito,
At 30 feet, or so, an 80 meter dipole has very
little, if any, directional properties. The 40 meter
antenna will have some, but not the 80.

Ron, W7MRR,

You stated " You could save yourself some money by just
taking a piece of coax and attaching a heavy duty 50 ohm
resister to the end of it, submerging it in oil
[commonly called a dummy load] and transmitting on it."

Wrong! Baloney! (My reply -- and it still stands). It may
have been tongue in cheek to you, but to some of the less
'antenna wise' hams reading this news group it may have been
taken as gospel. Fortunately, the rest of your post
indicates
that you speak from emotion rather than knowledge and that
your opinions should be taken very lightly.

You further stated
"This antenna is a really poor performer."

On what do you base your statements? It is an adequate
performer to say the least. I was more
than happy with it. You don't get something for nothing,
and a compromise antenna always
has some drawbacks. The ability to go from band to
band or frequency to frequency without
the need for retuning was great. A few comments
on e-ham does not reflect the hundreds
which B&W sold.

Further, you stated
"If you find a ham claiming they have worked 200+
countries with this antenna, make a bid for his QTH
because he has to be located on an island
surrounded by water or on top of a salt mine.
In other words, any good experience with this
antenna is due to the QTH and not the antenna."

I worked over 200 and lived in two different
locations neither of which provided me with a
good ground.

You continued
"The terminating resister in this antenna is used to
give you the 50 ohm match, just like the dummy load."

I must agreee that the resistor (600 Ohms) was part of
the matching system, but not as a dummy load even if
it did dissipate part of the power.

In your second message you said
"Irv just made it clear that his experience with the
antenna was "down from other antennas"
which is what I would call poor, but for what I must
assume are sentimental reasons, he thinks it is a
good antenna. So, for those of you who want an antenna
that is "down a bit," here's your chance to
get an under performer. Just tell them Irv sent you!"

I said 'down a bit' -- but quite tolerable considering the
saving in space and tuning time. You can call it poor if
you wish, but after your previous statements I doubt if
anyone will take your opinions on antennas seriously.
Even the best antennas can be underperformers due to
various factors. The B&W performed as stated by the
manufacturer and did well for me.

Referring to e-ham reviews you said that it "doesn't
do very well with most hams that have purchased it.
It is rated 3 out of 5 (5 being very good)"

e-ham reflects only a few of the hams that purchased it,
-- not 'most hams that have purchased it.",
and 3 out of 5 isn't bad. A number of good antennas have
been panned on that site.

The pro's and con's of this antenna have been well discussed
on this site. When a ham asks for advice, he does not need
biased opinions from someone who has only read about the
antenna (as I suspect of you), and gross exaggerations (like
a 50 ohm resistor on the end of a piece of coax submerged
in oil)!

Enough Already!!!

Source record: 148196

Having heard an A/B comparison of this antenna I concluded it was a very poor performer. It was at least 5 and maybe as much as 10db down from a dipole. So yes you do get quite a bit of frequency agility and don't have to use a tuner but it's like a dummy load with a wire attached. So if you plan on getting one then buy a 1KW amp to go with it to overcome it's lack of gain vs a dipole. I think the military proably liked it because they could change frequency without a tuner.

3611. Re: Mast grounded-help with coax

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-21 00:45:57 UTC
From: Uncle Peter <radioconnectionNO@cox.netSPAM>
Message-ID: <9rXc8.3535$XT1.97431@news1.east.cox.net>
Source record: 148197

The coax is probably a lower impedance for a lightning return path than the
#8 copper ground wire. You should bring the coax down to the ground rod,
and ground the coax to the ground rod as well. All of your ground rods
(service
entrance, radio antenna ground rod) should be bonded together. You can
use a coaxial lightning arrestor to provide the ground termination for the
coax
to the ground rod.

80/40 dipoles at that height really don't show too much directivity.
The one at home should have worked just as well. Maybe the band cdx
were worse or you had a problem with coupling to other wires, etc..
I've used 80m dipoles as low as 6-10 ft off the ground with good
results to regional stuff. With the average 35-40 ft dipoles here at
the house,I've worked dx many times. I once was talking to a guy in VK
on 40m, and we switched to 80m as a test. We still had no problems,
although the strength may have dropped a bit. I was only using 100w
and a parallel 80/40 dipole on one coax feed. I've worked many dx
stations on 40m with fairly low dipoles. Usually CW in the low end of
40m. I've found you can do it on 80m also, but an amp helps. Depends
on the noise. I've worked into the Caribbean and South/Central America
with a 160m Z dipole at 40 ft with 100w. The ends of it were probably
20 ft. Thats like a 20/10 ft dipole on 80m. In the end, for hi angle
stuff, like 40 day/ 80 night, the low dipoles almost always work
pretty well. Even real low to the ground like under 10 ft. That just
happens to fit my usual time sked, bands, etc...:) My average camping
dipole is about 10-15 ft off the ground. I usually don't have the
trees around to do much better than that. MK

No doubt. A bird can do a lot of damage to a plane that is really
moving. Most airlines have speed skeds to reduce damage from possible
bird strikes. IE: Below 20,000, stay under 300 IAS. By the time they
get down to 14,000 or so, they slow quite a bit. Some is ATC induced
of course, but also partly is birdstrike damage avoidance. You have to
be down to 250 knots when passing through 10,000 anyway. MK

Try to build your own. Take small metal can (that's one of your electrodes),
fill with sand and graphite powder mixture, push in second electrode, flat
or round and that's it. You will have to play with sand/graphite ratio a
little, fine tuning by position of the second electrode.
I used this method for few kW applications as a "quick and dirty" field
solution.
Have fun,

Message-ID: <a51l76$4154g$1@ID-124126.news.dfncis.de>
Source record: 148201

I am grateful to all who gave me a fast warning.

Got rid of it within 10 minutes. Ran the program a second time to obtain a second all clear. But I still feel dirty.

The final proof remains to be seen when I pluck up enough courage to send an e-mail to a guinea pig.

My sincere apologies to the unknown number of people who contracted it via me.

In addition I have erased everything from my address book plus a lot of other stuff which included messages waiting for replies. Again my apologies to those expecting a reply.

99.5% of my incoming mail is spam. 70 percent of it comes from the far east, Taiwan etc., in Chinese characters or really wierd indecipherable stuff. I get 20 or 30 spams per day.

For months I have automatically deleted all e-mails with attachments. But but before final dumping I inspect in case there's one which I am certain is OK to at least read the message. So far as I can remember I have not opened a non-OK attachment for months and months. And I have opened only 1 attachment of any sort in months.

To a knowledgable person only -

Off-topic Question 1. Is it possible to contract a virus other than by opening an attachment ? I have IE and OE.

Off-topic Question 2. If I have contracted a virus is it possible for me to infect my own website when I upload files to it ?

There may be others interested.

I have not uploaded anything to my website for 3 weeks.
Regards, Reg G4FGQ

I'm not sure if this is what you are looking for, but try "the RF Connection"

website is "http://www.therfc.com/antenna.htm", they call the product "KevWeave". I've seen the stuff(they are a vendor at many local hamfests).

The easiest way to describe it is a kevlar rope with a copper braid wrapping, similar to the braid on coax.

I considered getting some of this stuff for a quad project. It's fatter than "litz" wire. Its also a bit pricy.

Amen. Try either Agent or the free version, Free Agent. Neither one will spawn viruses because they print only plain ASCII text - no HTML, no Java, no whatever the latest craze is. Been using it for about seven years and no problems at all.

I have Outlook Express on my computer and every now and then I download the latest upgrade and fire it up to see if I'm missing something. The answer is always no.

In case you haven't done so already, check under "scrap metal"
in the yellow pages. I went to a scrap metal dealer near me for
tubing, and came home with a Gonset GSB 101 linear amp for
20 bucks. Needed 4 811A's and the rectifier tubes, but I replaced
them with 12 1N5408's & the thing works fine. But I digress.
That place has all kinds of tubing - maybe you'll get lucky and
find something near you.

Emphasizing what others said: the NEC does not give you any
choice on this - it *requires* that the ground rod you installed for
the antenna be bonded to the service grounding system.

Yes. Depending on your email reader config, scripts can be embedded in the
email that will run when the mail is read. These scripts could access
files, run apps, change system configuration, etc.

>
> Off-topic Question 2. If I have contracted a virus is it possible for me

Yes. If you have a cold, does it go away when you go to your friends house?

However, most web hosting sites have professional Admins who are a lot more knowlegable than the typical end user and usually have tools in place to contain/eliminate any threat to their systems.

I build a lot of stuff from aluminum irrigation tubing. Besides
buying it used from farmers, you can buy it new from the
national chain "Rain for Rent". I just called them today
coincidentally to get their latest prices. The smallest they
have is 1 1/2 inch for 0.84/foot. The biggest I got a price
for was 5 inch, .078 wall for $4/foot. It is 3004-H26 with
a yield strength of 24,000 PSI. Available in lengths to 40 feet.
I use Texas towers for smaller stuff.

Hi everybody,

I am a student currently doing a project on triangular patch antenna.
I used Ensoft Ensemble to simulate my design. I have came up with two
design on triangular patch antennas which are single band (bluetooth
freq) and dual bands (suppose to meet IMT2000 standard, but can't).

Realised that my knowledge on this type of antenna are too little,
just want to know more about its theory. So wandering anyone of u know
any website/URL do have the information i want?

Thank you.

You can get it much cheaper if you buy it used.
I built a quarter-wave for 3.900 MHz, and the tubing
cost almost nothing compared to all of the other stuff
(guy anchors, guy cable, insulators, cable clamps, etc.).

3628. open wire feeders questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-21 07:29:46 UTC
From: AB Brown <abbrown@nospammail.com>
Message-ID: <a527k7$hq5$1@slb1.atl.mindspring.net>
Source record: 148216

I've read a lot about the low loss of open wire feeders and I am thinking of running it from a G5RV or similar dipole back to my house. The length of the feeders would be anywhere from 50 to 75 feet to the house entry point. I have a couple of questions:

1) How are open wire feeders affected by objects, such as aluminum rain gutters, shingles, and antenna mast, which it will run near? How should I position it to avoid these?

2) If I use the open feeders to continue beyond the house entry point, the lines would have to run through the attic and then drop down through a hole into the radio room. Total distance from house entry point is 35 feet and it would pass many objects in the attic. However, I am thinking of using RG 8 coax from the house entry point to the radio room. What is the best solution here?

3) I've read that a tuner is used to match the feeders to the radio. What type of matching system would be best for the conversion of the open wire to coax at the house entry point?

I hope to be able to use this system as an all band dipole from 80-10 meters. I have always used standard RG 8 coax for my feedlines and I am a novice when dealing with open wire feedlines. Appreciate any advice given.

Thanks,
AB

Now all Cam needs to do is set up some basic stamp logic and some drivers
for the relays. The input to the stamp would be output from a SWR sensor.
Using good make-before-break logic, he could have autoadjusst of the
relays - on the fly while changing frequencies.

I use Netscape, and it has the ability to turn off JavaScript for email messages. (Careful people also leave it off when visiting web sites.) I'm sure IE has the same capability, and I highly recommend leaving JavaScript off for email. While some web sites depend on JavaScript to function properly, I know of no reason for an email message to contain JavaScript -- except to spread a virus.

I highly recommend ZoneAlarm, a firewall by Zone Labs (http://www.zonelabs.com). It can be set to detect all outgoing communications. This will alert you if a virus, or sleeper program like Back Orifice, tries to contact the Internet from your machine. This will at least let you know you're infected, and will prevent you from unknowingly sending infected messages to others. There's a free version that's very capable.

Incidentally, my ISP recently adopted the practice of deleting any incoming email containing exe or some other attachments, before it even gets to me. I don't like this very much, but it's an increasingly common practice. Consequently, when I email an exe file to someone I either zip it or change the extension in case the recipient's ISP does this. But I no longer see the virus-containing emails that I used to get with great frequency.

Hi,
my humble answers to your questions are:

> 1) How are open wire feeders affected by objects, such as aluminum rain
> gutters, shingles, and antenna mast, which it will run near? How should I
> position it to avoid these?
Quite much. Twinleads and open wire feeders should run at a distance
from any objects (the more from conductive objects) given as at least
five times the distance of the two wires. Ten times the distance will
be certainly better...

> 2) If I use the open feeders to continue beyond the house entry point, the
> lines would have to run through the attic and then drop down through a hole
> into the radio room. Total distance from house entry point is 35 feet and
> it would pass many objects in the attic. However, I am thinking of using RG
> 8 coax from the house entry point to the radio room. What is the best
> solution here?
I recommend you to convert to a coax before the house entry point.

> 3) I've read that a tuner is used to match the feeders to the radio. What
> type of matching system would be best for the conversion of the open wire to
> coax at the house entry point?
Connect the coax at a low-impedance point, i.e. at the current maximum
of the twinlead. Do not forget a current balun (set of ferrite rings
on the coax or a "coax coil") to prevent currents on the outer surface
of the coax braid. See http://www.qsl.net/w5dxp/notuner.htm for more
info.

You can always try the Old Timer's Light Bulb Technique for a quick "dummy" for HF. The filament in a light bulb has very little inductance. For high power, just put a bunch in series parallel. Another "Trick" similar to the graphite "Can of Sand", is to use Salt Water. When it starts steaming, it's time to QRT. I wonder if you can add Salt to brake fluid or mineral Oil directly? Another "Trick" good for fishing expeditions is to bury two rods in the earth separated so that you get 50 ohms. An SWR analyzer will help.

Another thing to consider is that winds isn't always horizontally polarized, as evidenced by a MicroBurst in my back yard that left 5 huge Oak trees felled in random directions on top of each other, but 100' away no damage at all. Vertically polarized wind spells death to Yagi's, although Circularly polarized winds probably cause the most damage.

On Two meters, I'd think a yagi would be way more effective, and less far hassle
than a phased vertical array. Turn it on it's side for vertical polarization,
and put it up on top of your house.

I've had viruses sent to me in the last week or so. One was:
A message you recently received from "<tlendrickmotors@cleanweb.net>"
with the
subject "the sound barrier in "
contained one or more viruses that could be disinfected.

Another one was:
A message you recently received from "<x8dp@PRODIGY.NET>" with the
subject "Now when our land is troubled,"
contained one or more viruses that could be disinfected.

The viruses have been removed, and the disinfected files are attached
to this message.

Yes, but doesn't happen too often. I hear some of the newer ones can
do that.
>
> Off-topic Question 2. If I have contracted a virus is it possible for me to
> infect my own website when I upload files to it ?

Only if the files uploaded are infected. Likely are not. The virus you
have is a macro virus. It's mainly raiding your address list and
playing e-mail gremlin behind your back.
It's not a file virus per say..

HI AB,

1. You Will have to keep it away from any metal 3 times the distance of the
spacing of the Line.. IE: if it 450 ohm line you'd need to keep it a minimum
of about 3.5 inches. away from conductive materials.

2. Run the coax to just outside the house and use a 1:1Current balun to
make the transistion. 35ft is allot of coax in this type of setup and may

degrade the performance some . but should still work on most bands.
I'd use the best coax I could afford for this , Hardline or flexiable 9913
stuff.

3.Most good T networks will work for what your Proposing.

Good Luck,

There are some viruses that don't need human interaction. The last
couple of years have centered on "exploits" of OE, and it took
Microsoft 2 years to finally get their shit together and give the user
the option to turn off "e-mail preview".

OE is the reason I've been a fan of text-only e-mail clients.

Any e-mail sent as an HTML document appears as HTML source code to me,
which I just toss in the Trash.

>
>Off-topic Question 2. If I have contracted a virus is it possible for me to

No, unless you embed an ActiveX control that's a virus. That too can be thwarted, turn off ActiveX in IE. Thought the downside is, you won't be able to immediately go to Microsoft Windows Update, but they do have an option to download the ActiveX control, if it's your first visit there.

Of course. That is obvious (to those who know antennas). That is how
the far field radiation pattern is constructed. Different rays from
different parts of the antenna add up with different phases.

The professional experts can't agree on a definition, so how can the
amateur experts?

If I could find some good latching RF relays, I would do that. The problem with nonlatching relays is that they must be kept powered which is hard to do when power goes down. If I power them from my backup battery system, my emergency power time decreases. I am happy with the knife switches mounted in my window. I can throw the switches faster than I can operate an antenna tuner.

Open-wire feeders should be kept at least a couple of diameters away from
anything conductive.

Thanks to all who contributed to this thread. The main issue here was not that I'm cheap :-)...its
more of an issue with space at the operating position for a large tuner and secondary to that I guess would be convenience. I did get some recommendations on some tuners that are fairly small that might fit in ok so I guess I will look into that. Cecil your approach is interesting...

Thanks again,
Harry

AB Brown wrote:
"How are open wire lines affected by objects---?"

Adversely.

"I am thinking of using RG 8---."

Good idea

"What type of matching system would be best ---?"

The 19th edition of the ARRL Antenna Book has suggestions in chapter 25.

Belden 9913 has a matched loss per 100 feet of 0.1 db at 1 MHz, 0.4 db at 10 MHz, 1.3 db at 100 MHz, and 4.5 db loss at 1000 MHz. Below 30 MHz, the loss isn`t bad.

A G5RV or similar dipole with a flat 100-ft line has less than 1 db line loss. You won`t often have a flat line, but the increased SWR won`t often kill your operation.

If you want to avoid coax radiation, use a balun at the antenna.

Best regards, Richard Harrison, KB5WZI

I use IE version 6 combined with a shareware program called
AdSubtract. AdSubtract allows me to filter several items
(Advertisements, Animations, Auto refresh, Pop-up windows, Background
images, Background music, Cookies, Referrers, Java applets and Java
script). I can set up different sites with all or any the above items
filtered. This is handy for going to some sites where cookies, for
example, are required.

Having a slower ISP connection it also speeds things up quite a bit
because you aren't loading all that stuff.

There is a freeware version and a shareware version. Originally I had
tried the freeware version and after using a short time decided to buy
the better version.

The learning curve is small. If interested you can check out their
site at: www.adsubtract.com

For email my ISP has incorporated email filtering with Postini. Any
messages which appear dangerous are held at the Postini site and a
message is sent to you advising you that there are there. You may then
go to the postini site and review them without downloading then on
your computer. The drawback is Postini only filters message coming
from out side your ISP. Any messages coming from someone on the same
server are not filtered. For that I have Norton Anti-Virus which I
check for up dates every other day.

Now and then something has slipped through, but for the most part I
have found this to be effective.

3647. Rhombic for tv reception

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-21 14:36:36 UTC
From: Barrett Richardson <barrett@phoenix.aye.net>
Message-ID: <20020221143636.75574.qmail@phoenix.aye.net>
Source record: 148133

Anybody have experience using small(ish) rhombics for broadcast
tv reception? I've spent a couple of weeks searching at google
for information about the same and haven't found much. The few
reports that say they work great really didn't give much
detailed information. I've put up a small one (10' by 5'10")
and it works, but not fantastic. I'm considering a larger
one, 1 wl on a side for channel 2 -- about 28' total length,
but if I can't get better performance than a consumer grade
Deep Fringe antenna I could probably find a cause more worthy
of the effort. I have a Wineguard pr-9032 which is the best
consumer grade UHF I could find (16 dbd on channel 30) and it
outperforms my scaled down rhombic, and my small rhombic outperforms
the low end VHF/UHF combos (on UHF but not VHF).

I know what you meant, Richard, but to be precise:
If you want to avoid coax radiation, use a balun at the coax
to ladder-line transition point in a G5RV type antenna.

If you are using 450 ohm ladder-line and you feed the system at a current maximum point on the ladder-line, any ladder-line SWR between 4.5:1 and 18:1 will translate into a 50 ohm SWR of 2:1 or less which, IMO, is a good enough match and requires no antenna tuner.

Finally got the A99 vertical running and now I am going to try the MQ2 Hybrid Quad since I am limited on space. I remember these antennas from years back when I though they looked like they wouldn't work. After research I find that they do work very well. I have not been able to find anyone who can say anything bad about this antenna in the reviews. Thought I would see what all here know about this antenna before I purchase it. Anyone dissatisfied?

Thanks

Source record: 148145

Ideally, open wire and other twin lines should be kept more than three times wire-spacing away from ANYTHING.

Beyond three times there's no detectable improvement. And for a feet of line it hardly matters what the spacing is between the line and its surroundings.

There's nothing special about conductive materials. Materials such as non-conductive timber also have DIELECRIC loss.

Here's some food for thought -

Run the feeder nearly touching a copper sheet and there will be no significant extra loss.

Run the feeder nearly touching a very thick polyethylene sheet and there will be no significant extra loss.

There will be only a decrease in Zo which may necessitate moderately different tuner settings.

Source record: 148144

Barrett Richardson wrote:
"I`ve put up a small one (rhombic) (10` by 5` 10") and it works, but not fantastic."

It`s too small, Arnold B. Bailey in "TV and Other Receiving Antennas" has a design I posted here. An Aussie built it and reported it worked as advertised.

"Description: Four straight horizontal conductors forming a diamond"

"Size at 200 MHz: Two #10 wires each 36 feet long, separated 18 feet at midpoint, overall length 31 feet"

"Transmission Line: 300 ohms balanced"

"Resistance at Center Frequency: 600 ohms"

Antenna Average Surge Impedance: 600 ohms"

Physical and Patterns: Can`t reproduce here

"Gain at Center Frequency 14.5 db (or less)"

"Frequency Bandwidth: 1 db down, 30%,
3 db down, 100%"

Rhombics are usually 4 or 5 wavelengths on a side at the design frequency. Bailey`s rhombic is 4.5 wavelengths on a side at 246 MHz. You could expect more than 14.5 db gain at higher frequencied and less at lower frequencies. The sides are about one wavelength at channel 2.

Best regards, Richard Harrison, KB5WZI

Cecil, W5DXP wrote:
"---to be precise: if you want to avoid coax radiation, use a balun at the coax to ladder-line transition point in a G5RV type antenna."

Exactly. I did say as the questioner said, "or similar dipole".

We have a different mindset and mine included avoiding a transition, regardless of the G5RV benefits, between balanced and unbalanced line.

I assumed an unbalanced coax connector on the radio, an unbalanced tuner, and an unbalanced coax line all the way to the dipole. A balun might be inserted there if the user felt so inclined.

Cecil`s system is superior. Some, though, may find it more trouble to implement. Avoiding a tuner may be a big plus with the CAM System.

Best regards, Richard Harrison, KB5WZI

Ron

I have an MQ2 on the roof of my house. It doesn't work as well as a bigger aerial and is probably only marginally better than a dipole. It has disadvantages as any compact, loaded aerial does. I have had plenty of contacts with mine however including all continents on 20m, 17m and 15m.

It has a fairly narrow bandwidth but my autotuner can match the feeder OK across the bands - works best at resonance as you would expect.

If your expectation are slightly above a wire dipole you will be happy. If you expect the thing to function as well as a full sized two element you will be disappointed. The MQ2 is however a LOT smaller than a full sized two element. I also have a Force 12 C-3SS and this is more than two times bigger in length and width than the MQ2 - the Force 12 works great but I couldn't put it on top of my house!! If the MQ2 is the biggest thing you can have then it will probably be fine for you.

Oh and by the way, I worked a fellow in the states (I'm in England) who also had an MQ2 except his was only 12 feet off the ground on a temporary pole and mine at about 45 feet! So they do work.

Good luck with your decision.

There are strategies to reduce their coming to you (noted frequently
here by a tag line following the poster's closing noting "remove the X
in the address to send me e-mail"). This is to tackle the problem at
the outset (scanners reading these messages, finding your address and
sending you spam).

The etiquette of this varies with those who feel put upon to remove
that X....

The alternative is to run barefoot and take care of the problem at the
receiving end. Use filters to send the spam to the trash can (still
does nothing however about the download time spent before taking out
the trash delivered).

>Off-topic Question 1. Is it possible to contract a virus other than by
>opening an attachment ? I have IE and OE.

That is the "feature" of OE, it will start that attachment as a
"service" for you (**** you very much MS). The Hackers just love this
and it is the principal form of epidemics that rage through the
internet in a matter of hours.

Disable the feature! Unfortunately for the last security bug admitted
to by Microsoft it also mean disabling most of the browser when you
pull that particular plug (I am thankful MS software does not run life
support systems).

>
>Off-topic Question 2. If I have contracted a virus is it possible for me to

>infect my own website when I upload files to it ?

Yes and No. This is strictly dependant upon the nature of the virus. Some run on only MS/Intel platforms. Many servers run on Sun or Apache software on non-Intel hardware. For them, the virus dies immediately (lack of oxygen).

Then you have MS servers that would not only support this virus, but have there own vulnerabilities (they don't need to wait for your virus as they already have been hit directly by hackers - it's just so easy).

Most virii are of the Macro construction tailored for OE and the Office suite. This is the argument MS makes about their browser being tightly wed to the operating system. This is a nice idea - if they understood the concept of monoculture suicide when a single infection can be transmitted across the entire platform.
>
>There may be others interested.
>
>I have not uploaded anything to my website for 3 weeks.
>Regards, Reg G4FGQ
>
>

Hi Reg,

It is highly unlikely that any infection has been transmitted across to your web site. The reason is that the software to port your pages to the host do not support those same macros (they don't care one way or the other; unless, of course, you use MS Office software to do the porting - sigh - another "feature").

However, once a virus has hit, it may carry what is called a "trojan horse." This is a variant that is an executable program (other than application macro and the macro may have installed the trojan horse) that is designed to pick and choose when and where to attack. These are most often called DOS attacks (denial of service). That is, your machine will run this program automatically and without your knowledge. The general characteristic is it wakes up, looks at the clock and if it is not "time" goes back to sleep. In other words, it is wholly transparent to you and does nothing disruptive to your machine.

When it IS time, it and 1000's like it in infected machines across the net will come alive and start sending requests to a targeted site to overload that site's capacity to respond to those requests and the requests of legitimate visitors to that site; hence the term denial of service (no one gets anything done). And still, you are not directly affected; that is, there is no outward appearance of infection.

The net result is you may read of a popular site being closed down by hackers, and there will be nasty e-mail coming your way, identifying

you as the accomplice! To remove this infection requires doing a "sweep" of your system to test for unauthorized, running software.

The trojan horse may also monitor your activities and report them to the source of the infection. Feel like making a purchase at e-bay? This program will look over your shoulder as you fill in your credit card information. Guess where this information is off to next? This is best defeated with a "firewall."

A firewall monitors all requests from or transmissions to the internet and works on predefined rules that will nip any suspicious activity in the bud (my firewall is from Agnitum and is available for free as a beta currently). Oddly enough my firewall reveals there is a considerable amount of "attempted" traffic from my machine to Microsoft! I, of course, nip it in the bud (my own form of denial of service ;-).

As it is considered an extreme breach of etiquette to post attachments to this and many (other than pornographic) newsgroups; there is absolutely NO NEED to have a newsreader with OE "features."

Microsoft, as a service to you, has set the default options of OE to accept this behavior. If you feel it is inappropriate (and if indeed you were aware - we've already covered that ground), it is your responsibility to disable them. You may do exactly this only to have those over-ridden (as a service to you) with the next "silent" upgrade that was performed behind your back (providing of course you do not have that firewall).

Absolutely none of this happens with Java software unless you ask for it (do not confuse Java with that abomination Java Script). That is, Java software naturally assumes you are not promiscuous and have no taste for these shenanigans (the inversion of the MS security mentality - or lack thereof. MS considers you to be a whore, or encourages you to respond like one).

You may have eradicated the virus, but freedom from future infection is not guaranteed. As in life, this is a function of your choice in partners. Stick with the old routine and you will be infected again and again and again.... Weekly headlines prove that ad nauseum.

Break the cycle at the vector.

Hi Rick,

All you need to do is go down 4th into Georgetown to find scrap metal
vendors galore.

Also try Electronic Dimensions in Tacoma. They are located two blocks
down the hill from the Dome (424 Puyallup Ave.). This is a HUGE
warehouse crammed to the ceiling with surplus.

You can dicker with the owner Glen Galati (a Ham), but he may bend
your ear for 1/2 an hour to answer a simple question :-)
The store has limited hours and is not open Monday nor Tuesday and
only from 10-6 weekdays; 10-3 Saturday. He carries tons of test
equipment and even shielded rooms (transportables). He is a retired
Air Force procurement type who obviously still has contacts. One of
his funnier stories is how the soldiers from Ft. Lewis buy equipment
from him because he's cheaper than the normal channels (which have
surplused that same gear to him). This is about the ONLY practical
government rebate ever offered.

Boeing Surplus is a pale shadow of its days in the 70's when you could
find anything.

One thing it does is avoid high power expensive tuners usually needed
for amplifiers. That was my original problem. So tuner losses are
automatically avoided.

Another thing it does is avoid impedances that built-in tuners cannot
match. My new IC-756pro has a built-in tuner and my Ladder-Line Length
selector always presents the 765pro tuner with impedances it can match.

Another thing it does is minimize common-mode currents.

I am not a PE or structural engineer but my recollection is that the 80 MPH standard is a minimum recommended standard specified in ANSI/EIA 222-E and widely accepted in the tower manufacturing industry. The standard establishes a minimum windspeed and radial ice load that a tower should withstand if it is to me safely erected. I can't remember, but I think that 80 MPH is a category two hurricane, something that is not out of the relm of possibility anywhere in North America. Again, this may be incorrect. Just going from vague memory. Try doing a search on EIA 222-E.

I realize (I think...) that the best material used for winding traps or mobile coils is SOLID wire in varying guages, and preferably air-wound - but is there any data or test results when stranded, plastic coated wire is used - and wound over a PVC form? Sometimes what's "best" isn't necessarily practical - and I have some very nice stranded 16 ga UV resistant plastic encased wire I'd like to use for some 40 meter mobile coil experimenting I'm working on - but would hate to see what MIGHT be a good design seriouslt flawed by materials used.

Mind you, I'm prepared for SMALL compromises in end results - but would LARGE reductions in efficiency be expected to result from stranded/plastic coated wire? Yeah, I'm aware of potential heating problems at higher power levels...

Source record: 148161

It's not the function of Zone Alarm to detect viruses residing on your machine. For that, you need good anti virus software -- Norton is one of the most widely used -- and keep it updated. What Zone Alarm or a similar firewall does is intercept and prevent hackers from getting into your system via your Internet connection. My firewall has logged four attempts so far today, and four yesterday -- things are a little slow just now. Viruses, worms, trojan horses, and other malevolent software can be planted on your machine without your knowledge by this method, and firewalls like Zone Alarm help prevent this. But unlike most other firewalls, Zone Alarm also detects outgoing messages from your computer that might be sent by virus-like software that got implanted in your machine either via your Internet connection, by opening an email attachment, or by downloading and opening an infected picture, program, or other file.

You need at least one firewall and at least one good anti virus program to live with today's Internet. And none of these is perfect, so you should check often and keep an eye out for any unusual operation or any outgoing communication you can't account for.

Morse code?

The problem of prods in the soil may be adjustment for the desired load. A similar load may be the water load used by engineering labs at powerline frequencies. This is a guillotine which can be inserted so that its diagonal blade can provide the desired resistance in contact with the water. With finesse, this might work at r-f.

At the shortwave broadcast plant, we used stainless steel wire to dissipate up to 50 KW. Problem with wire lines is the spacing between wires is too close for convenience at 50 ohms, even with multiple wires, usually. But, this can be gently transformed to almost any desired impedance with a tapered transmission line.

For 100 KW dissipation, we erected regular Copperweld wires in a parallel wire line a couple of feet off the ground with the spacing between wires adjusted for the desired impedance. We steamed out the worms with that one.

Best regards, Richard Harrison, KB5WZI

I gave Arnold B. Bailey`s TV rhombic data with the exception of the graphics. On the drawing is a 600-ohm termination resistor at the far end of the rhombic to make the antenna unidirectional in the direction of the terminated far end. The termination resistor absorbs energy coming from the direction opposite from the terminated end. Using a termination resistor may help get a cleaner signal.

Best regards, Richard Harrison, KB5WZI

Have you tried a long wire? Here in UK in the 50s they were used for
fringe reception. One version had a series of small capacitors in the
line, total length about 50 ft for 45Mc/s for London.

Winding trap coils for the 40 Mtr band out of stranded wire
is ok - the differance would only realy come to notice when
getting into VHF.
If the plastic coating is very thick, it means the turns cannot
be wound tight together so reducing the Q of the coil.
Again, at 40 Mtrs this would probably be of negligable influance.

Regards, Peter G0LRP
.

Source record: 148071

I have been experimenting with some 11m dipoles in my attic so I can see what will work before I take my morse test to finish up my general upgrade. I have to use attic antennas due to restrictions in my neighborhood. While I have been able to get decent results with one dipole I have made and put up, I am puzzled by this phenomenon that seems to plague me.

When I first put a dipole up there it ran along the frame from the peak of the roof down the frame. This dipole worked terribly, didn't receive, even worse on transmit. I then remounted one in the opposite direction, the first one (the bad one) went North to South as a sloper and the other faced East to West as a straight dipole. I tried the N&S scheme on 6m before too and got terrible results as well. I have yet to try it on the E&W. So my question is what could cause this to happen? Could it be do to the fact that the N&S dipole basically faces the sections of my house and attic that are covered by aluminum siding or is the sloping causing something to go wrong or.....?

I am open to any suggestions here. Thanks!

well first off.... DO NOT connect the MFJ directly to the radio (I heard of it being done and they toasted the MFJ). You can use a handy's "rubber duck" antenna on the BNC connector, place the unit in the near field of the antenna attached to the radio to be tested without contacting it. With the MFJ in Frequency Counter mode, briefly transmit on low power and take a reading off the MFJ's display. Oh, one thing... before running the test, it's nice to ask if the frequency is in use first (good operating practice)

The handbook has a nice idea. Two pieces of copper clad board with lots of 2 watt rsistors sandwiched between. About 50 of them in parrellel. The handbook has the values. This will dissipate 100 watts in air. Dunking it in mineral oil, ala Heathkit, and you can pump a lot more.

> Would it be possible to build one?

Yes. Almost ANY outside antenna would work, but you will have to get it up
at least 160 feet for line of sight to the aircraft on the ground 18 miles
away. The odds are you will be able to pick some of them up by reflections
from tall objects (like TV towers and such) but to be RELIABLE, you've got
to get some altitude on your antenna.

You can get a ballpark number from it, but it does not have an accurate
frequency standard, so accuracy will not be high.

You must live in some bumpy territory. I am 30+ miles away from the
local control tower - and their transmissions come in loud and clear.

On the other hand, there is a range of hills between me and an airport
about 35 miles to the North, and I cannot hear that tower at all.

"Covered with aluminum siding"? Covering the dipole isn't a good thing.
If I just read it wrong it could also be that (if it's tacked up to a beam)
the wood/roofing material's affecting your signal. If you're sure your
installation's correct, go back up and take a look with closer scrutiny at
it. You might see something you overlooked like bad connection, behind
metal flashing, etc.
I put up my first dipole against the side of a concrete wall. I never
thought, initially, what all the re-bar would do to it. I moved it a foot
or so and it was like turning on a light bulb (figuratively speaking).

Barrett Richardson wrote:
"Do you know if he was able to do any comparison between it and the best consumer grade antennas on the market?"

No. He did not say which antennas he had previously tried. He only reported poor signals before he put up the rhombic and satisfactory signals after the rhombic was up.

It`s been a year or so, but Bailey`s rhombic was what he said he put up. The 14 db gain figure versus a dipole (Bailey always uses dbd) is dependable and can be compared with gain figures for deep fringe antennas. The deep fringe antennas are likely to have gain quotations at their best frequency and be referenced to an isotropic which is a couple of db better looking than dbd. The rhombic figure is at 200 MHz, a Bailey standard practice. At higher frequencies, the rhombic has higher gain.

No one has mentioned height, but line of sight to the horizon is about:
D = square root of 2h.
D is the distance to the horizon in miles, and h is the antenna height in feet. TV broadcasters try to put viewers within their horizon by using very high transmitting antennas. So, height of the rhombic is almost unimportant except for getting the vertical pattern directivity down along the horizontal and not beamed uselessly up towards the sky. For this, 1/2-wavelerngth of elevation for the rhombic, or more, is satisfactory. 1/2-wavelength at channel 2 is only about 9 feet. So, that shouldn`t be too onerous.

Best regards, Richard Harrison, KB5WZI

I might give this a try. In the meantime, I use Eudora for email (an old version without ads), Free Agent for a newsreader and Netscape Communicator for a browser. If sites I visit require plug-ins for song and dance, I leave.

None of these applications share address books or anything else and they didn't come from Microsoft.

I also run ZoneAlarm, AdSubtract and Norton AV.

My ISP does a good job too of intercepting virus containing email. They stop Snow White from HAHAHA about once a week.

I don't get the Chinese crap anymore since I changed ISPs and email address. Unfortunately, I had a "mail to:" link on my home page and the robots found it so now I get a lot of crap via n7ws*@arrl.net. So I redirected that to a yahoo mail account where they filter off a lot of the known bulk mail.

To get even, I added a lot of 'mail to:' addresses for some of the more obnoxious spammers to my web page, so when the robots go looking they can spam the spammers.

I do not put my credit card numbers on the Internet. I know it's supposed to be safe, however, I remember a while back when Western Union had to ask about 15,000 folks to cancel their credit cards because of a "leak" in their web security. For sure, this was a hack _into_ their system and it could happen anywhere these data reside but it seems to me that it would be easier when the data are going and coming.

I know the hoops through which I had to jump when I was processing Secret data on a computer located inside a shield room with no connection to the outside world. From this perspective Internet "security" is a joke.

If an online vendor doesn't have an 800 number where I can speak to a human being and complete my transaction, they can ring up a No Sale.

My two cents.

>Would I be able to pick up the ground side of the transmisson (source is appx. 18 miles away) with an outside antenna?<

Sure--I hear Manchester NH ground traffic any time day or night from 35 miles away with some "Granite State" hills in between using a 11-dBi yagi at 35 feet. The airport and my house are both around 250' ASL. Propagation characteristics are about the same as they would be for 2-M weak-signal SSB--with the small inherent disadvandage of using vertical polarization thrown in. In order to cheat mother nature and hear over the horizon, you'll need some gain plus height to do it (a rubber duck has negative gain and...well...duckish height). I have a small 3 element broadbanded design that might work pretty well for you at chimney height over a 18 mile path. If you're really interested, I can E-mail you a Word file that describes how to build it.

3703. Re: Rhombic for tv reception

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-22 03:41:29 UTC
From: "J. McLaughlin" <JCM@Power-Net.Net>
Message-ID: <u7bfdusid27b1@corp.supernews.com>
Source record: 148091

A full 40 years ago, when doing vhf propagation studies in West Virginia
(a story unto itself) I spotted a rhombic antenna in a front yard.
Everyone on this group knows how we can spot antennas that can not be
seen by mere mortals. Turned the car around (a task on those roads) and
took a better look. Yep, a miniature rhombic. Could even see a
resistor at the far end from the house. Knocked on the door. Upshot
was that the son-of-the-house had been in the military working with HF
and brought some "learning" home.
It was common to see very long transmission lines from a house to
the antenna that was placed at a hot spot. I am here to tell you that
propagation in such terrain is very interesting.
So, yes. One may and can use a rhombic to receive TV. Not good
value for a radio amateur at HF even if one has the room. 73 Mac

Why not borrow, buy or make an inexpensive whip (Radio Shack usually has some sort of telescopic antenna on a BNC connector). Adjust it to 1/4 lambda (23" ?). Then clamber up onto the roof of your house and see if you can get any signal at all. If you can get a weak signal, then it might be worth building an outside antenna. If you get nothing, then you'll have to try harder (Yagi, preamp, tower) or give up.

I built my neighbour (retired pilot with a float plane) a sleeve vertical dipole out of cheap coax cable (LAN coax) and put it in a length of PVC pipe. He clamped it to his chimney (yes, I know...) and it worked for him.

He was in the same situation (no 'Tower' signal in his kitchen using handheld), except only about 10 miles.

Screaming Skull,
Could be several things, ranging from an improperly made dipole, to there was just nothing to hear. The most probably reason is that the 'siding' is shielding the antenna. Making the antenna 'slope' wouldn't have much to do with it, it does make an antenna sort of directional, but not directional enough to cause what's happening to you.
Just as an experiment, take the antenna outside, hang it up high enough not to 'cloths-line' your self, and see what happens. If you still hear nothing on 11 meters, there's something wrong with the dipole. If you do hear stuff, then the attic location just ain't gonna work...

Pedro,
The MFJ259 frequency counter is not very accurate. I
would not try to determine your transciever's frequency
by using the '259. You can use your transciever to check
the accuracy of the '259, though. Just turn on the transciever
to a known frequency, then tune the '259 till you hear it
on the transciever. Compare the two frequency readings and
see how far off the '259 is. There's no need to transmit
at all.

A lot of advice (and good advice) says to keep the feedline away from
other metallic objects. At my shack, I have absolutely no choice but
to run my feeder line through two holes I drilled in the bottom
portion of my metal window frame. The feeder line crosses the window
frame at a right angle as opposed to running parallel with the frame.

I do keep my rats nest of cables away from the short piece that
connects to the tuner just before the feed line goes outside.
Otherwise, I'm not sure what impact this has but I've been on the air
for years this way. I guess my point is, if you must run the feed
line near metal, keep it to a minimum!

I have found some old radio books that include designs for TV reception:
Antenna Manual, By Woodrow Smith is one.
This one sized for FM radio reception centered on 97 MHz
multiply dimensions by 1.5 for channels 1 to 6
for channels 7 to 13 (highband!?!) multiply dimensions by 0.5
overal length= 55'-9"
sides of diamond = 30'
Distance across center = 22'-6"
minimum mounting height = 10' above obstructions, 30' min, 40' perferred
two 390 ohm terminating resisters
matching section (I can't describe...) but important to 300 ohm twin lead.

Wes, playing Devil's Advocate for a bit, why would you trust a completely unknown clerk-person at the end of an 800 line with your credit card number when you won't trust a reasonably secure encryted transfer from your computer to another? I know, none of my business, but just curious . . .

I never feel easy about even handing my card to a waiter in a restaurant - we have no way of knowing how many cards have their info copied, etc.

A few years back at one of the finest restaurants in Dallas, I paid the tab with my credit card, and we waited and waited for the waiter to return with the receipt, etc. After about 20 minutes, I pursued the matter and was told with a big smile that "Gee whiz! Somehow your card has gotten misplaced after we posted the transaction, but don't worry, you can call and cancel it" or words to that effect.

I just looked at this person for a moment and then said calmly "You have five minutes by my watch to place that card in my hand. If you do not, at that time I am calling the Dallas Police Dept. immediately. Now get moving!"

About three minutes later, the card had mysteriously been "found."

I think that we are in far greater risk when we mail a check to someone which contains all the numbers some people need to harvest your account and make solid inroads on stealing your identity.

Cruel world, isn't it?

Yes indeed. I have over 3000 feet (2 and 3 inch) that I bought for about 20
cents/ft used. I just missed getting another bunch of it for FREE.

|
|It`s too small, Arnold B. Bailey in "TV and Other Receiving Antennas"
|has a design I posted here. An Aussie built it and reported it worked as
|advertised.
|
|"Description: Four straight horizontal conductors forming a diamond"
|
|"Size at 200 MHz: Two #10 wires each 36 feet long, separated 18 feet at
|midpoint, overall length 31 feet"
|
|"Transmission Line: 300 ohms balanced"
|
|"Resistance at Center Frequency: 600 ohms"
|
|Antenna Average Surge Impedance: 600 ohms"
|
|Physical and Patterns: Can`t reproduce here
|
|"Gain at Center Frequency 14.5 db (or less)"
|
|"Frequency Bandwidth: 1 db down, 30%,
| 3 db down, 100%"
|
|Rhombics are usually 4 or 5 wavelengths on a side at the design
|frequency. Bailey`s rhombic is 4.5 wavelengths on a side at 246 MHz. You
|could expect more than 14.5 db gain at higher frequencied and less at
|lower frequencies. The sides are about one wavelength at channel 2.

The problem with Rhombics is the terrible sidelobes. Without careful design the first pair can sometimes be bigger than the "main" lobe.

The Laport double parallelogram version can do much better in this regard. I have modeled one in Eznec that has the largest sidelobes (the thirds) down about 12 dB with F/B >20 dB. Free space gain is about 15 dBi. This is with an overall length of about 60 feet at 144 MHz or a bit under 9 wavelengths.

Modeling this is tricky because of the multiple wires at the feedpoint and loads and the number of wires meeting at acute angles and/or crossing. I used segment tapering on both ends of all wires and then had to tweak slightly to get the

number of segments below 500 (the Eznec limit)

Rhombics were very common for TV use back in the 40s,50's. Then the
yagi's and log type designs took over because people wanted to watch
more than one channel and could spin them around. I have a QST article
about TV rhombics somewhere. It was from the 50's I think. A fairly
large "yard sized" rhombic has a lot of gain on VHF. Probably more
than many of todays "TV" antennas being most are compromises to cover
such a large spread of frequencies. MK

Dear Friends:

Yesterday night (in Spain) was the first time i used it and today i have discovered that input button is a little hard, so i have to press it strongly in order to switch into Frecuency Counter. I have found correct what some of you told me about accuracy. "It gives to you an idea, but not a precise count frecuency".

By the other hand it is very simple to use for adjusting antennas, i have adjusted one in few minuts. The disapointment in front of MFJ259B is that the 259B has an internal microcontroler which make a lot of calculations, so it gives to you direct readout for many variables, which in 259 you have to hand calculate (for example: Capacitance or inductance).

Thanks to everyone
Have a nice time.
Pedro

> the effect you are looking for.

The gain vs. stacking distance is quite broad. Gain will maximize between 50-60"
(this through modeling and test range).
Closer distances will not distort the pattern- it will remain eggshaped as is
the case for all shortened dipole type omnis, but the stacking gain will not be
realized.

This sounds like other 259's I've worked with. I'm not impressed with
the switches and buttons they use. Both mine and my friend's 259 have
bad range switchces (the main rotary switch). Some positions you have
to wiggle the switch to make it settle in, others you actually have to
hold the switch to keep it in connection. On mine, the mode button
is completely flakey. Their debounce curcuitry isn't working at all.
It steps through multiple modes each time I press. It's like playing
a slot machine to get this device into the right mode.

Wes, N7WS wrote:
"The trouble with rhombics is terrible side lobes."

That`s true with Bailey`s TV rhombic, too. It has side lobes about 40, 50, and 75 degrees either side of the main lobe. If other TV signals on the same channel are in these directions, they may interfere.

There is significantly more gain in the main lobe than in any side lobe. So, you`ve improved S/N over an omnidirectional antenna in any case.

Rhombics are good antennas. They are the most often used commercial antenna for point to point application. This, because they are simple and work over a wide frequency range without tuning or adjustment. Rhombics are not ideal, but give good performance over a wider frequency range.

Best regards, Richard Harrison, KB5WZI

Others have addressed your questions so let me offer a different suggestion. Faced with the same problem many years ago, I drilled a 3/8 hole in the roof just over the attic access portal in a closet and made a vertical dipole out of a CB whip from Radio Shack and a 10' piece of conduit. This let me poke the whip up thru the hole at night and draw it down out of sight when not in use. That was then. Now I'd get one of those 35-ft collapsable masts from MFJ.

When the HOA finally noticed I pointed out that the rules only forbid *attaching* antennas and this one wasn't "attached" in the legal sense*; that it was like a portable BBQ grill vs a permanent backyard fireplace. I promised to get rid of it if they outlawed BBQ grills. There was mucho sniveling but the antenna stayed, tho I was careful to take it down when not in use. Natch YMMV but I'd think the same arguement'd apply to any "unattached" structure.

*"attached" has a well defined legal meaning. For example, If I rent a house from you and hang a picture on the wall the picture is still mine cuz its not "attached" but if I "attach" (glue) paneling to the walls it becomes yours and must be left when I move out. No, I ain't no lawyer nor very bright ... but ah kin read ;o).

Good luck, KA3DWW

3721. Multiband dipole - trial and error results

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-22 14:21:49 UTC
From: Bob Cook <captcook@compuserve.com>
Message-ID: <a55k78$9ta$1@suaar1ab.prod.compuserve.com>
Source record: 148109

All,

Re designing and building multi-band HF dipoles.

I have been using multiband dipoles for HF operation some years now with good success. At present I use two. One is a multi-conductor, (four conductors), single cable design, which I use vertically on a 50 foot sailboat. Another is a multi-wire set of dipoles which I have installed in my condo attic for home operation. I am getting ready to make a new single cable multi-conductor antenna for the attic and in experimenting with calculating and verifying resonant lengths and finding some puzzling outcomes. I am sharing my findings here in the event someone else has experiemented with single cable, multic-conductor dipoles and cares to share their findings and insights.

Other posts have been made to the forum discussing multiband dipoles and I am aware of those in the past 3 months or so, infact pacrticipated in a few of these discussions. Please note I am not here interested in sets of mult-wire dipoles set at angles to one another, like 90 degrres, etc. I am primarily interested in designing and making what I will call single cable, multi-conductor dipoles.

Here are the details of the antenna(s) I am presently testing. I would like an antenna resonant on 40, 30, 20, 17, 15, 12 and 10 meter ham bands. The cable I am using is 5 conductor TV rotator cable. I bought a 100 foot piece of cable. My plan is to put the two antennas next to each other or at right angles to each other. I cut it in two pieces one piece for the 40, 30, 20 meter antennas and one for the 17, 15, 12 and 10 meter antennas. From prior experience I knew that each dipole would affect the resonant frequency of the adjacent dipoles but was not sure in what direction or by how much. I suspected each dipole would lower the resonant frequency of the others. And I suspected that resonant frequency of the shorter, (higher frequency) dipoles would be most affected.

As a starting point using the formula 468 / frequency mhz), I cut all the antenans 8% too long, ie for a frequency 8% below my desired resonant frequency for each antenna. I then connected the antennas, one at a time to my tranceiver using a very short, (2 feet), piece of 75 ohm balanced feedline. I then ran SWR and foward vs reflected power tests. I carefully created a table noting the desired resonant frequencies, the design length by formula, the design length plus the 8% allowance, the predicted resonant frequency with the 8% additional length, and then when tested the foward and reflected power for each antenna. I also noted the sharpness of the resonant dip for each dipole. My intent is to find by calculation and trial and error to trim each dipole down to bring each one to exact resonance at my desired resonant frequencies.

The results so far have been partially as predicted and partially quite puzzling. Testing antenna 40, 30 & 20 meter antenna the 40 and 30 meter resonant frequencys were lower than predicted. The resonant point of the 40 meter dipole was low by 10%. The 30 meter dipole was low by 3%. The 20 meter antenna had no dip, ie no resonant point within 30% of the predicted resonant frequency. Hmmm..what happened to the resonant point of the 20 meter dipole?

The 17, 15, 12 and 10 meter antenna had a similar result. That is the resonant point of the 17 and 15 meter dipoles was 3-8% lower than predicted, and this time there was no resonant point for the 12 or 10 meter dipoles within 30% of the predicted resonant frequencies. So again, I am puzzled as to what happened to the resonant points for these two dipoles?

That's it...comments?

David Jackson wrote:
"---matching section (I can`t describe...)---."

A tapered line is the usual matching section for a rhombic. Like the antenna, iit is not particularly frequency selective.

The spacing at the driven end of the rhombic is chosen to work with the feedwire size to produce an impedance equal to the characteristic impedance of the rhombic. Insulators which gradually shrink in length as they descend in altitude on the feedwires are used to space the feeders. At the transmission line altitude, the spacing is the same as the transmission line. It`s a done deal.

A tapered line could have been used by Bailey to transform his specified 600 ohms at the center frequency down to the 300 ohm feedline he specified. He must have thought it wasn`t worth the trouble. The spacing between twinlead wires is very small, but larger wire and spacing could have been used in the downleads. But , the antenna works as specified.

Best regards, Richard Harrison, KB5WZI

3723. response to feeders question and a new question about dipole support

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-22 14:39:45 UTC

Source record: 148110

Thanks folks for all the informative responses. It looks like I should be able to use open wire feeders after all. I like the W5DXP design as no tuner is used, except I would have a problem finding an appropriate place to mount the "ladder line length selector". I wonder if I could use relays in place of the switches he uses? Can anyone recommend a specific brand of relay that works best?

Now my next topic involves antenna support. The only way I can mount a 130' dipole at the 37' height is to use three supports- two for the ends and one for the center. Even with this, the ends of the dipole will have to be bent so about 15' hangs vertically at each end. I've been thinking about using three 20' 6 inch by 6 inch posts to start with, with tv mast extensions to 37'. The posts would be buried approximately 4' into the ground, with the masts extending about 20' above the top of the posts. There are three questions that come to mind here: 1) Can the three post with mast extension system be successful without using guy wires?
2) Will the dipole interact with the masts and, if so, how can I avoid this?
3) Are there any plans found on the web showing the construction of a 35-40' self supporting wooden mast?

Lastly, as I really didn't want to throw in yet another question, can anyone suggest a website or provide instructions for the proper ground insertion of the wooden post/ mast system I describe above? Things like... is 4' depth sufficient, should the posts be surrounded with concrete, etc.. just general mounting instructions.

Again, thanks in advance for all responses.

Hi Mike

review of the MQ2 I thought you might like to read.

Andy

Ron

I have an MQ2 on the roof of my house. It doesn't work as well as a bigger aerial and is probably only marginally better than a dipole. It has disadvantages as any compact, loaded aerial does. I have had plenty of contacts with mine however including all continents on 20m, 17m and 15m.

It has a fairly narrow bandwidth but my autotuner can match the feeder OK across the bands - works best at resonance as you would expect.

If your expectation are slightly above a wire dipole you will be happy. If you expect the thing to function as well as a full sized two element you will be disappointed. The MQ2 is however a LOT smaller than a full sized two element. I also have a Force 12 C-3SS and this is more than two times bigger in length and width than the MQ2 - the Force 12 works great but I couldn't put it on top of my house!! If the MQ2 is the biggest thing you can have then it will probably be fine for you.

Oh and by the way, I worked a fellow in the states (I'm in England) who also had an MQ2 except his was only 12 feet off the ground on a temporary pole and mine at about 45 feet! So they do work.

Good luck with your decision.

Mark Keith wrote:
"A fairly large "yard sized" rhombic has a lot of gain on VHF."

And, it scales to HF.

For shortwave broadcasting, we might be ordered to transmit to a new country, or on a band for which we had no curtain antenna, or on a band in which all our curtains were in use at the scheduled times.

We coukd throw up a rhombic in a few hours and blister the new target with signal. A nice feature was being able to use the rhombic on any frequency between 6 and 17 MHz without touching any antenna tuning adjustments. Yes, the width of the target covered shrank as frequency rose. Yes, more of the signal overshot the target as frequency rose. But, as Cecil observed, halitosis is better than no breath at all. Sometimes, we even used the rhombic outside the usual 6 to 17 MHz range, and they still worked.

For program relays, we used only rhombics on both ends of the circuit. There were just too many frequency changes needed to keep on top of changing propagation to always get the best signal. We used triple frequency diversity and were perpetually shifting to lower or higher frequencies. The order wire was busy saying: put this language or that language on the next higher or lower frequency, that is, one of the three frequencies simultaneously carrying the program relay of that language at the moment.

For broadcasts you only make scheduled program changes. You must announce your schedules over and over in advance so listeners will know where to look for you. The schedules are based on propagation predictions and you have to be there whether there is propagation or no propagation because these conditions can change rapidly. The curtain antenna can serve well. You will be broadcasting for hours on the same frequency. You can adjust matching networks in advance of frequency changes when another curtain will resume service. That doesn`t work well for program relay.

Best regards, Richard Harrison, KB5WZI

Tapered lines are neat. Traveling waves on transmission "don't like" step changes in Zo (discontinuities); when they encounter them, reflections are generated. But when the line Zo changes smoothly and gradually, the waves are "tricked" into thinking all is well.

We used a lot of waveguide tapers when testing Phoenix missile transmitters and receivers. Because of size constraints, the missile waveguide was 1/4 height and of course the test equipment was all full-height WR-90.

I have one of the six band models and find it quite good mounted on my roof. If I could have a big antenna, I would put up a tower and a Quad or maybe one of the new Stepper Yagis from Fluidmotion. But the QTH just won't allow it.

If the MQ2 is all you can put up, you will not be sorry you did. It has good front to side, fair front to back and decent gain. The bandwidth tunes just fine with the autotuner in my rigs. I have run a full KW into it without a problem. Country count is now 295 after 2 years.

This may be some good news. An example of a station I'm after is
15.2kw antenna 78 meters above ground 72 miles away on UHF
channel 27. For comparison I can get a fuzzy unwatchable picture
picture from a channel 50, 26.2kw at 100 meters, 55 miles away
with the smallest UHF/VHF combo Radio Shack sells. The FCC
data for the channel 50 shows a field value of about 0.3 in
my direction. The Wineguard pr-9032 gives only a marginal
improvement on channel 50. With the Wineguard I can also ascertain
there is a channel 27 there, but this may be deceptive because
there is a much stronger channel 27 about 100 miles distant to
the rear. On the same tower as the channel 50 and about the
same height there is a channel 24 with 10.9 kw but a 398kw
channel 24 is about 45 miles to the rear. The stronger channel
24 to the rear disappears with the 10ft rhombic pointed opposite,
but I still can't get the other channel 24. My small Radio Shack antenna
and Wineguard both just get the channel 24 that is to the rear,
so the f/b ratio of a rhombic helps in that regard. I had blamed the
mediocre improvements of the Wineguard's performance on lack of height
(it's only at twelve feet) and was in the process of figuring out how to
get a larger temporary rhombic 30 ft off the ground for testing without
lots of labor. If I can worthwhile information by testing for UHF
reception just a few feet off the ground, that is definitely good news.

AB,
1. More than likely, you won't have to guy the masts with the provision that you increase the depth you 'plant' them in the ground.
I think you would be 'better off' with a mast slightly shorter than
you planned, than not getting them deep enough.
2. The antenna will interact with the metal mast to some extent,
but probably not enough to really make any difference. Keep the feed
line away from the mast (wood or metal), you may be able to adapt the
old TV twin lead stand-offs to work with ladder line.
3. The 'HandBook' used to have an artical about making wooden masts.
I haven't looked for it lately so have no idea if it's still included.

No idea about finding how much to bury a mast, but the local power
company suggests/recommends about 15% of the pole length, up to about
eight feet deep. I would think that something around 5 to 6 feet should
'do' for a 30 foot pole. I don't think concrete would be necessary, but
I would definitely coat a wooden pole/mast with some type of preservative.
Maybe creosote (if you can find it) or tar.

Good luck with your installation. If it works well, you can come
and do mine!

I wrote: "---put this language or that language on the next higher or lower frequency."

This was a request from the receiver site to the transmitter site to change one of the three frequencies carrying a program relay. I insinuated that propagation caused changes, but that`s not all. The spectrum is sometimes an undiscplined place, so the receiver site checks the repertoire for a clean frequency that can work when interference alights as it too frequently does. Three viable frequencies are needed at all times so that the triple diversity reception works properly.

Yes, but you are receiving the reflections off the hills, not a direct
signal. You can talk elebenty-bazillion dB gain on your antenna, and given
no line of sight (with an error correction for diffraction) you won't hear a
damn t'ing. I garontee.

That's a simple question to answer...

Given average diffraction from a clean horizon, line of sight range is given as:

range = sqrt (2 * (antenna height))

Where range is in miles, and antenna height is in feet.

Given that the aircraft on the ground have an antenna height of 6' or so, and at 18 miles range, we can solve the equation backwards to give the fact that the antenna has to be up about 160' to get this kind of range.

The news could be better. Do you have an obstructed path? A mountain between you and the transmitter?

78 meters above a "plane" earth surface gives a horizon of about 22 miles. Your horizon needs to be 50 miles to total 72 miles. Your antenna would only have to be up 1250 feet if there were no path obstructions.

The atmosphere bends and scatters radio and TV signals but reliable over the horizon transmission requires huge antenna gains on both ends of a path in most cases.

TV receives a wide band, up to 6 MHz. More signal is needed to compete with noise in so much bandwidth. Radio usually occupies less bandwidth and takes less signal for satisfactory reception.

You will have anomalous propagation which provides occasional long distance reception, but don`t count on it.

Best regards, Richard Harrison, KB5WZI

Hi Chaps !

Thanks for the info ...

I am considering buying one of these and was wondering about performance.

I have an SGC SG235 500w auto ATU, in your opinion do you
think I may be able to add this to the antenna and use it to expand
the usable bandwidth of the antenna without having the ATU in the shack ????

This way I won't have the losses of a high SWR on the coax ... in theory :)

Please CC me direct if you reply as my news provider isn't too reliable :)

Your SWR won't be high enough to make a diiference. My max is 2.5:1 on the upper end of 20 meter fone. It is 1:1 at 14.058.

I think the disadvantage of having a heavy tuner mounted up on the boom is far worse than a little SWR on the feed line.

Hi Craig,

Thanks for the swift reply !
I thought the band width on 20m of the antenna was just a few tens of kcs
???
If you are getting this sort of bandwidth then I have to agree, forget the
ATU !

I'll be driving into the antenna with a valve based linear amplifier so an
SWR of 2:1
won't be a problem !!

Cheers and thanks for the info.

Really wasn't goint to attempt line of sight. Get 15 stations clear
now, have line of sight on only two of them.

Getting the weak channel 50 from so far beyond it's horizon on a
continuous basis just got me wondering if I could snag a couple
more about 15 miles farther out. If such a thing exists, I think
I'm in kind of a local sweet spot. I've always gotten better
reception than others in the locality and have a smaller and
shorter antenna.

"Jim Weir"
>... given no line of sight (with an error correction
> for diffraction) you won't hear a damn t'ing.
> I garontee.

Yes, but isn't there almost always some amount of diffraction (or creeping waves, or some other mechanism) given typical terrain ? I have a feeling that would be difficult to eliminate all non-LOS (but almost LOS) paths completely. I have read of many examples of non-LOS paths being used with simple application of ludicrous amounts of antenna gain.

I visited a ham in Halifax, NS that had a 20' homemade dish that he used for Moon bounce (600 watts out, 0.4 dB NF in). On the 440MHz band, he could talk to hams in Saint John, NB "...anytime I want to..." over a path of about 150 miles. He was on a bit of a hill, but not THAT high.

Obviously, this approach may not be applicable to the original post.

That was the nice thing about tube PAs with PiNet tuning, light bulb loads were easily matched.

IMHO, MFJ products certainly do plumb the depths of poor quality. I'm sure you have heard the old joke MFJ = Makes F* Junk.

I've got an MFJ 12V Power Strip that had been labelled backwards and then repainted and then relabelled. The backwards labels were still obvious under the paint.

I bought an MFJ Noise Bridge - very poorly built. The 9V battery wouldn't stay in the holder. The battery holder was right on the circuit card. Just too cheaply built and not worth the price charged.

Message-ID: <20020222182001.21783.00000146@mb-mq.aol.com>
Source record: 148037

I think I misspoke. I just tested again and my SWR measured here in the shack at the end of 50 feet of coax is:
14.001 2:1
14.058 1:1
14.100 2:1
14.200 5:1
14.350 is 6:1.

According to the chart in the ARRL Handbook, the additional loss in 100 feet of RG8A is only 1db at a 6:1 SWR on 20 meters. I dare say that is not enough to worry about.

SWR on other bands is better
21.000 2:1
21.058 1.5:1
21.100 1.4:1
21.200 1.3:1
21.300 2:1
21.400 3:1
Additional loss at 3:1 is 1/2 db

I have no problem with my "valve based" linear - an Ameritron AL572. But the antenna manufacturer does warn you to reduce power if the SWR is above 2:1. An ATU won't help you with that because the concern is the antenna itself and the ATU won't change the SWR on the antenna.

However, I can say that I have run the full KW with no ill effects - so far. I have only done it for short periods of time when I needed the extra power to snag some new DX. I'll bet you could melt the coils if your ran big power at high SWR for too long.

Hope this helps

Jim wrote--

>range = sqrt (2 * (antenna height))<

Jim's simplistic response trolls a deeper question. If this "rule-of-thumb" were literally true, why would anyone bother constructing a station for weak-signal VHF work? Those 100-mile-plus schedules we keep on non-open VHF bands simply couldn't happen. Right?

To resolve the mystery, I recommend starting with the ARRL Antenna Book on page 23-9. This primer offers a good introduction to the dynamics of station gain vs. path loss. I won't burn a lot of bandwidth paraphrasing it, except to note that receiver sensitivity, transmitter power, antenna height and gain at both ends of the path, bandwidth, and S/N all play important roles in overcoming the very high path losses that exist over the horizon.

I believe Jim is correct in pointing out that VHF OTH work does depend heavily on bending and scattering. However, this "concept" involves much more than bouncing signals off rocks--and it is a highly reliable mode (been around for decades).

Many of today's scanners and airband HTs sport 1-uV or better AM sensitivity (superior to those $2000+ NAV/COM radios sitting in the airplanes). Couple weak-signal capability with a modest directional antenna on the roof, and I promise you'll hear a lot of stuff not visible outside the window. :)

Hi

I have a MQ4 on my tower at 50ft. I also have a pair or alpha delta
dipoles, the 160/80/40 and the LBPlus (80-10). On all bands from 20M
and up, my mq4 is quieter and exibits directionality (obviously, a
full size beam would be better but, this is what I am using. I am
satisfied with it. It is rather narrow in band width but any good
antenna tuner will sort that out. I have had mine up since November
and seems to be surviving quite well.
I am also only 25KM from TGM and I know the owner. Quality workmanship
and top components go into each.

Enjoy it.

> In fact, how does one use a radio telescope to measure the required brightness? Is this *easily*
> done?

For the case of an extended source such as the 'galactic center', the apparent brightness spectral
density is measured by dividing the power spectral density (watts / (meter^2 - Hz)) at the antenna
aperture by the solid angle (steradians) subtended by the receiving antenna beamwidth. Of course
corrections are required for antenna and transmission line efficiency, and the introduction of
corrupting noise by various sources. The antenna beamwidth can be determined from first principals
though calibration on a test range is usually required if an accuracy of better than a couple of
decibels is required.

> I take it that such brightnesses are measured over surfaces rather than points.

Correct. Brightness is a surface property and is of little meaning unless the object can be resolved.

> How does one
> find the (necessary) power over the surface of an object? I would think the resolution of amateur
> radio telescopes would be so low as to make it very difficult to measure the brithness of an object
> like Mars or Jupiter.

First measure the power spectral density (watts / (meter^2 - Hz)) at the telescope antenna. Then
divide by the solid angle subtended by the object, typically determined separately for planetary
objects using optical telescopes. Most planetary objects are roughly spherical and may not radiate
uniformly in all directions (not lambertian), so the calculation actually returns the brightness of an
equivalent lambertian radiator.

3759. EZNEC modeling of GAP Voyager DX antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-23 04:00:42 UTC
From: jdicso@aol.com
Message-ID: <20020222230042.18464.00000124@mb-mk.aol.com>
Source record: 148047

I need help modeling the subject antenna. I'd appreciate advice on modeling the following:
1. Spacing of linear loading rods don't meet minimum criteria for segment lengths. Any work arounds?
2. Source coax is inside lower vertical tubing and connected to terminals in the gap. Can this be handled by Transmission Line only?
3. A coax stub is inside the upper vertical tubing. Length is increased by adding a capacitor at the top. How is the coax modeled? How is the capacitor modeled?

Thanks, Jim K2SZ

Amazing that MFJ is still in business. Their Tech support must be working overtime when an additional dollar per unit invested in higher quality would of solved the problem and stopped the phone calls. I wonder how much MFJ spends average per unit sold in returns and phone time trying to convince customers to keep the junk? Also assuming they wanted to sell a quality product, you'd think subsequent versions would of solved the problem.

I would steer clear of Cushcraft. From what I've heard and from what I've read
on the newsgroups lately, they are the WORST company for customer service.
Customer service is a big part of buying a product, so even if you have to pay
a couple extra dollars for another brand, I wouldn't buy Cushcraft.

I have been buying and using MFJ equipment for many years. I guess I have been one of the lucky ones as I have not had problems with any of them (yet.) I have looked inside some of them, and the soldering scared me so bad I just closed it back up quick! :-) Of course 30 years in aerospace manufacturing and quality assurance tends to make one rather critical of workmanship anyway. The problem is, "where are you going to buy this stuff if not MFJ?" It's the only game in town for much of what they make. I just grin and bear it.

Have you heard of multi-element helicals? It wont help your sidlobes, but
you might get some more gain. You have only 1 wire, so put in a 2nd antenna
wire 180 deg. from the 1st, or 2 more wires 120 deg.s apart.
You don't have a metal ground plain, so how about a sheet of some metal
instead of a plastic bucket? Keep the antenna element off the gnd. plain
w/ heat shrink tube?

> for much of what they make. I just grin and bear it.

What pisses me off is that they seem to go out of their way to make it cheap. They seem to like to use specially manufactured ultra thin metal for their homemade cabinets. Some of their products can be crushed like a beer can. The screws that hold the lid on always seem to strip out the case because they use such an aggressive thread pitch so that they can put the screw in with three turns instead of six turns.

Some of their products look tempting, but these are the sorts of issues that aren't visible in advertisements. I've learned my lesson. They always seem to find a way to "exceed their customers' expectations" (surprising the new owner with imaginative and creative elements of poor mechanical design quality).

Maybe they could have a "Deluxe Line" of products (for which they would charge the extra $0.50) and not make such strenuous efforts to cheapen the design.

Sorry to rant, but the world would be a better place if they did something to improve their product design standards.

Some new stuff and some updates since last month....
found at http://www.ab7sl.com

1. NEW - Cushcraft R7 / R7000 page.
includes black box photos and component values
w/schematic also R7 / R7000 instruction and assembly manuals
Note: (all downloadable too..)

2. Prescott, Arizona Page has many all-new photos

3. Equipment Photos Page has some all-new photos added

4. Downloadable DXCC List updated - 16-Feb-2002

5. AB7SL - DXCC "Need List" - pls check it out....

6. Weather Page has real-time conditions for 12 selected US cities
and links for complete USA / World real-time weather data

Aw geez, guys. Come on now. I don't know squat about antennas, dipoles, wavelengths, or any of that stuff. I guess I should have mentioned that. I'm not trying send signals to Mars, I was just curious if an external antenna would help.

I don't know if the db loss will shorten the wavelength of the dipole which will cause me to have more frequent bowel movements. But I did get some very useful information that will help me stick something outside my window that may, I repeat, MAY help me pick up more of the communications than I currently am.

If it doesn't, I won't complain. I promise.

'nuff said?

Hello Peter,
The entire site is tested with the current version browsers from Microsoft IE6, Opera 6, and Netscape 6. All pages including the W9INN Page are fine with these browsers....

If you are using an older browser (especially Netscape) then you might want to upgrade since many sites now use up-to-date html that was devised long after these older browsers were released.

The site is however 'optimized' for IE 6 (as it says on the home page) since over 90% of my visitors use Internet Explorer.

According to the access statistics for Google:

http://www.google.com/press/zeitgeist.html

MS IE 5.0, 5.5 & 6.0 are EACH about three times more popular than Nutscape.

As I said earlier on this same topic:

"I too use an older version of Netscape and I'm damned tired of cybergeek web
page designers that assume everyone has the latest software, a 1 GHz processor
with 1 Gbyte RAM, a 35" monitor, a dedicated T1 line and wants to look at their
product via streaming video.

If these folks want me as a consumer, they are making a big mistake.

There are few nice things to say about the nation's telephone companies anymore
but one of them is that they understand backward compatibility. You don't have
to buy a new telephone every six months to keep making phone calls. In fact your
old 1950 rotary dial handset should work just fine.

Telephone companies are run by business people who realize that they need to
keep *all* of their customers, not just the ones with the latest whiz-band
super-duper handset with a 1 GHz processor, 3-D video and your choice of
"designer" color."
|
| The site is however 'optimized' for IE 6 (as it says on the home page)
|since over 90% of my visitors use Internet Explorer.
|

99.999% of the phone companies' customers use tone dialing handsets, but the
companies still accomodate pulse dialing.

Likewise. I haven't seen much to complain about in MFJ for decades.
The first stuff they came out with was real junk, and earned them the
well known Mother X-ing Junk name. I remember hot glued pc boards, in
hobby boxes, etc. But when they came out with the first mass produced
TAPR 2 TNC clone, things turned around. There were some cheap tuners
out there from MFJ, but you get what you pay for.

As for the 259, I bought mine used, and it has worked flawlessly for
many years (even after it fell off the truck at 50+ MPH). No problem
with the push buttons at all, and have only had to clean the rotary
switch one time, something you would normally expect on a device that
doesn't get used very often. Oxidation happens.

My only regret is that I don't have one of the newer ones with digital
readout and more functions.

Unlike the "1 GHz processor with 1 Gbyte RAM, a 35" monitor, a dedicated T1
line..."
...IE 6.0 is a free download. I suspect that Nutscape updates are free too.

Excuse me for putting it so simply: Old software sucks. New software
sometimes sucks too, but old software sucks more.

At work: Windows 95, etc. Pure hell. Constant crashes. Garbage.
At home: Windows XP, etc. Easy. Stable.

Wes:

I am not trying to talk you in to upgrading your software or your processor. You might find this interesting, however. I asked a company which is a fairly major vendor of out-sourced web design why they ignored older browsers. The answer was that folks with older browsers tend to NOT be on-line buyers (they gave me some comparative statistics which I do not remember and never knew from whence they came). If this is true and the purpose of the site is to sell stuff (as opposed to merely increasing hits), then ignoring older browsers might well make business sense.

Again, I'm not looking for a fight here.. just passing along the information (such as it is) in case you or anyone else is interested.

Paul

Don...after all this drivel...

Go buy yourself some Radio Shack RG-58 coax off the bulk spool in the back of the store. Don't use that prepackaged crap on the racks. Buy enough coax so that you can reach the point on the house where you want to mount your outside antenna, plus a few feet.

Put a BNC connector on one end of the coax. Strip the outer black sheath 22" back from the open end. Use an icepick to open a hole in the braid (without breaking too many of the braid wires). Snake the center conductor/insulation out this hole. Get yourself a piece of dry wood or plastic pipe about 4' long. Staple (or cable tie) the end of the center conductor/insulation to one end of the wood/pipe. Staple the end of the braid to the opposite end of the wood/pipe.

Fasten this contraption to your outside house mounting point using string or rope. Orient it with the wood/pipe vertical and the center conductor/insulation at the TOP of the wood/pipe. Run the coax away from the antenna at right angles as far as you can, at least 24" or so. See if you can hear what you want to hear.

If you can, THEN start reading all about how gain antennas work and all that stuff. If you can't hear what you want to hear, gain antennas aren't going to buy you a lot, as you will be listening to a lot of noise even if you can pick up more signal with the gain.

In the case of netnews readers, Netscape 4.6 is a lot better behaved
than Netscape 6.2. For some reason, using Netscape 6.2, my news server
keeps asking for login and password, over and over. When replying to
netnews postings, Netscape 6.2 puts in a lot of unneeded unnecessary
extra blank lines.

Hello Cam,
"Pete" is the invisible representative for the rest of us for whose sake we stand. Wes is such a whiner I thought it best to advise him (on Pete's behalf) to take a Valium....

Or ..... Wes could just drop out of the hobby completely - and / or - disappear from the internet.

the company that pisses me off is mosley
they take forever to get out any order no matter how big or small
i ordered a 9 ele 2 meter yagi from them it took 10 weeks to get it and i would
call up and ask about it nearly every week after the first month and they would
find all sorts of stories to tell me like out of boom stock or this or that
then when it finally got here i was so disappointed in its construction and
materials and how much of the construction i had to do that i never did get the
thing together
then to make matters worse i have a mosley 6 meter vertical and i needed an
aluminum wire part of the hairpin match i called them up and wanted to place an
order for that part and i asked them how long it would take to get the part and
they said about a week i said cool and your sure it wont take 8 weeks like before
they said no will go out end of this week
well it took 8 weeks to the day to get out a 1/8th diam aluminum wire about 3 feet
ling
what a terrible company

3793. Relays for the Ladder-Line Length Selector

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-23 20:35:39 UTC
From: CAM <Cecil.A.Moore@IEEE.org>
Message-ID: <3C77FD1B.79D13D4@IEEE.org>
Source record: 147981

I've got a few inquiries about using relays for the ladder-line length selector. Relays will work but they have the disadvantage of consuming power in order to perform their function. (I'm working on the concept of using small model airplane servo motors for this function that won't require continuous current but I'm not a mechanical engineer.) The relays that I have successfully used are:

Omron, LY4-12d - these relays are four pole double throw and ideally suited for 100 watt RF stuff. Four are needed for a 0-15ft LLLS and five are needed for a 0-31ft LLLS.

I was lucky enough to find a bunch of P&B MR11's at a surplus store in Phoenix. They aren't made anymore but worked very well in a 500 watt system inside a dust-proof enclosure.

I also used P&B KUP-11D15-24's that I obtained for $2 each at a surplus store in Silicon Valley. They handled 500w nicely after tuneup at 100w. I modified the common contact wire such that it exited the relay through the plastic dust cover top rather than at the base of the relay.

Since I don't like the current drain associated with the above relays, I presently use ten DPDT knife switches obtained from a surplus store in Tucson for $2 each. They are mounted on a piece of plexiglas that is mounted in my hamshack window just above my transceiver, amp, and power supply. I can switch the knife switches quicker than I can tune an antenna tuner as I have a chart on the wall with the previous tuning information - no tuner required.

3794. Need 40/80M Antenna Advice

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-23 20:49:49 UTC
From: Richard Lubash <2k-plus@2k-plus.com>
Message-ID: <230220021549494265%2k-plus@2k-plus.com>
Source record: 147982

I live on a wooded 1 acre lot that makes it very difficult to put up wire antennas (lots of 2nd, 3rd growth scruffy trees between the tall ones). I have a 50 foot tower mounted to the house with an Alpha Delta 40, 80, 160 double sloper on the tower with a Tennadyne 10 el log periodic for a top hat and a separate Fritzel FD4 Windom that I switch between for 40 and 80. I do Ok with these antennas but I am looking to do better. I have thought about the Force 12 vertical dipole for 40 or possibly the Butternut HF2V with a medium radial system for 40 and a little bit of 80. My question, would either of these be an improvement (receive & transmit) over my existing antennas or if not any suggestions that don't involve stringing long lengths of wire through the dense foliage.

Thanks,

Richard / N1VXW

> If you can't hear what you want to hear, gain antennas aren't going to buy you a lot, as you will be listening to a lot of noise even if you can pick up more signal with the gain.<

Let's see, dangling a dipole fed with cheap RG-58 from a broom handle is a better plan for hearing the tower because mounting a directional antenna on the roof and feeding it with low-loss cable will just pick up a lot of noise. Did I get that right?
Glad you straightened us out!

Let me just add one word "Consumer" software.
That's the stuff that comes with a Microsoft style warranty - 'we guarantee that this product might, perhaps, perform more-or-less as advertised for maybe 90 days, and if it don't it's your problem not ours, even if we know it is faulty'.

Can you imagine trusting your money, or your life to that sort of stuff?

Professional software continues to run the world as the generations of consumer stuff evolve. Air Traffic Control, Banks, Telephone companies etc. etc. are quite happily running on stuff older than some of the posters.

Before I retired, the organization I worked for made a practice of locking new business software releases in the vault, unopened, for six months to let some other poor sucker find the bugs - we had corporate subscritions so got all the upgrades.

Serious operational software - the stuff that did important things as opposed to pretty things - was professionally tested for at least six months before anyone was allowed to install it on anything other than a test and evaluation system. If it was modified or upgraded it went back for the full test and evaluation process.

And now, back to HAM radio; which thank goodness, does not have the same hang-up about last year's radios.

Dave
Used to be a software geek, but grew out of it.

3798. Re: Aviation antenna question

Source record: 147987

The simple answer is that, unlike other radio services using VHF/UHF;
Air Traffic Control has no interest in communicating with stations on
the surface at more than a few miles - usually just on the airport.

Therefore their antennas are selected and positioned so as to provide a
clear path to aircraft. They don't normally place them up on high hills,
or worry about obstructions which will limit surface coverage. As long
as they are 'line-of-sight' to aircraft in the airspace they are
interested in their requirements are met.

The aircraft on the other hand have a large 'line-of-sight' coverage
which can easily exceed a 200 mile radius for high level traffic on Jet
Routes.

In other words, you may be able to hear aircraft from long distances but
most likely will not hear ground transmissions for any significant range
- there will always be exceptions due to the occassional antenna site on
top of a hill, or some anomalous propagation.

I can hear some ground transmissions from a site some considerable
distance away (its on a hill), yet several busy airports much closer are
inaudible despite high, or even active ourdoor antennas.

It's just the nature of AVIATION VHF/UHF systems.

>I was just curious if an external antenna
would help.<

The answer is yes:

1. An external antenna will help.

2. An external antenna with some gain will help a little more.

3. An external antenna with some gain that's fed with low-loss feedline will help even more.

4. An extenal antenna with some gain that's mounted above the roof and in the clear (and fed with low-loss coax) should help quite a bit. It should help because every improvement you make in your antenna system will enable your radio to capture more signal and less noise.

> yet several busy airports much closer are inaudible despite high, or even active ourdoor antennas.<

Everything you say about Ground Stations is true...which is why I find it challenging to pick them up.

High helps, but "active" may hurt, especially if your feedline doesn't have a lot of loss to begin with. Many after-market preamps are noisier than the front ends in many of today's radios. Also, a preamp can easily overload your receiver's front-end with strong out-of-band signals. I use a GaAs FET preamp on my airband yagi, but I also have a passband filter built into the magic-T that knocks down the out-of-band stuff. The system would probably work virtually as well without the preamp.

Directional gain usually helps a lot more than active gain because--among other things--directivity rejects much of the surrounding noise energy that would otherwise compete with the desired signal.

|Excuse me for putting it so simply: Old software sucks. New software
|sometimes sucks too, but old software sucks more.

Really. When I retired a couple of years ago, my department was still using HP-9836 computers running HP Basic or Pascal to control dozens of HP-IB instruments and collect and process test data on missile hardware from such as AMRAAM and Tomahawk.

You can be damned sure we didn't do this over the "productivity enhancing" network that the company hired Computer Sciences Corp to install and maintain. It ran the latest and greatest Windows NT, which I dubbed "Not Today", which described when it would be up and running.

The HP machines were using at most 1M of RAM and often no more than 512K. That's "K" not "G". The problems if any, where usually with the buggy firmware that HP put into the latest-and-greatest instruments.

But HP quit supporting these a long time ago because it's not good for business. They need to sell new stuff just as Microsoft, Dell, Gateway, etc. need to do, so obsolescence is part of the business plan. And the foolish buy into the idea. I could go on about how planned obsolescence affects your very security and costs you a lot of tax money, but this isn't the place.

In closing I'll just report that my mother-in-law still has a dial telephone hooked up in her garage and it works every time.

Quality is the extent to which something conforms to specified performance data. If the performance is specified as being rubbish, and that's what you get, then that's high quality. Always look at the performance specification before buying. If it does not have a performance specification then don't buy it! Don't buy pigs in pokes !

I have some experience with using such antenna analyser instruments. They give the right answers with sufficient accuracy to serve the purpose intended. I have found them very useful. Their small physical size allows them to do jobs which to the bigger instruments would be impossible.

My only complaint is the purchase cost of such instruments. It is too high for what is inside the boxes. I have successfully used the instruments for several years. Design and development design costs must have been recovered some time ago.

From a users point of view it is time the sign +/- of X was displayed on the meter. The technology has been available for many years. Where is it?

Are manufacturers waiting until they have extracted the maximum possible profit from present designs before introducing bringing something "new" ?

3806. building a ground plane antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-23 23:58:07 UTC
From: tucansam@whodis.org
Message-ID: <a59aafmvl1@reader2.panix.com>
Source record: 147995

Hi everyone.

This is my first dive into antenna building, thus I am very green. Please forgive the simplistic nature of my questions.

I am trying to build an antenna to grab 118.5Mhz, the tower frequency of an airport about 17 miles from me. I have a stick of PVC and some RG58 and want to build a simple, vertical ground plane (based on a response I got to a previous post).

I have one now cut to 26" and it performs reasonably well in grabbing stuff out of the air that my rubber duck never got. But I still can't get the tower.

Rather than cutting the coax to the center of the band I want to get, can I cut it to 1.97 ft (243/118.5) and hope to get any better gain?

If that doesn't work my next attempt will likely be a directional yagi, so I'll probably be back :)

Thanks!

Jason

Jason,
Not really. The length of th antenna you have now
is close enough so that if you were in range of the
tower, you should be hearing it (I'm assuming that it's
as high as you can get it). What will help more than
anything else is more height. Good luck...

> named ???

'MFJ Enterprises, Inc., was founded in 1972 by Martin F. Jue.' That's thirty years tops, not "forty some".

Are you claiming personal responsibility for MFJ's quality ? Wow....what a great newsgroup. Everybody is here...

Suggestion for senior management - increase prices by about a dollar or two per unit and aim the extra $ in the general direction of mechanical quality (traditional meaning - not that new ISO9000-hijacked meaning that allows 'consistent junk').

You don't need to make such efforts to make the cases cheap. Use thicker metal. Mount the battery holders to the case, not the PCB. Make sure the battery stays in the holder. Make sure the screws don't strip out the case. Put the labels on the right way the first time. If you make a mistake, clean it off completely - don't just paint over it. (Geezuz, I only have 2 MFJ products !!!!!!!!)

And finally, one doesn't have to operate their own company to be qualified to report on their own personal experiences with obvious and systematic quality problems. A well run company would be well advised to listen to their customers - especially their former customers...

Good luck.

Hello Bill and others....
This covered with a link you can click on to get the registration
email re-sent to you right away. Here is the URL.

http://www.eqsl.cc/qslcard/faq.cfm#Signup

Here is the text ...but you'll need to go the eQSL link above to use the
clickable link...

I registered but never got a Signup Code in my e-mail!

If it still hasn't arrived after 15 minutes or so (to account for
Internet delays), click here and we will re-send it to your e-mail
address immediately.
If your e-mail address had spelling errors, our fully automated system
will have received an e-mail about it. If you believe that is the case,
go here and you can correct the bad address and re-send your Signup Code
to you.

Good luck and happy eQSL'ing....

No argument from me, except that I would differentate between active
antennas (good ones that is) and preamplifiers with which I have found
exactly the limitations you mention.

I find my Dressler ARA-900 gives little problem on VHF/UHF, but some HF
actives can create an amazing bunch of garbage.

Dave

You're right - I was referring to people that like to run old and/or weird software (Nutscape for example) on their home PC and then complain incessantly about the problems that they experience.

> Professional software continues to run the world
> as the generations of consumer stuff evolve.
> Air Traffic Control, Banks, Telephone companies
> etc. etc. are quite happily running on stuff older
> than some of the posters.

Old 'Air Traffic Control' software is the worst of all. Extremely (!!!) inefficient routing algorithms - wastes billions per year. I've seen a website where someone had found a flaw in the overall design that could lead to small VFR aircraft arriving unannounced in front of a commercial transport at the boundaries between ATC zones. Rare but frightening. The new on-board Collision Avoidance Systems will help of course. It is such an ugly monster that the FAA is spending billions trying to make it go away. I understand that the Canadian ATC system is a great deal more advanced (smaller problem).

Telephone Billing Systems are pretty ugly too... Telephone Companies might be happy, but their customers may be less happy. I guess you know that foreign operators can put items on your bill that will take you months of begging to have 'forgiven just this once' ? There is often no practical way to deal with billing errors or bogus charges.

Seems to be something wrong with that URL as it doesn't have
an index.html. In general, vacuum relays would be too expensive.
After all, what I am saving is the cost of a high power tuner.

I hold a technicians license and have recently
been bitten by the antenna bug. (Insert
appropriate joke here.)

Anyhow, I want to start playing around with
constructing antennas. I like many others face
the debilitating handicap of being soldering
impaired. So to me it makes good sense to have a
SWR meter at the minimum, available to check any
antennas I make before using them on my handheld
and turning it into a mass of melted plastic with
little bits of transistors, resisters, and
whatever interspersed.

Anyhow, I just read the thread regarding the
quality of MFJ test equipment. Question
(finally). Who makes a good SWR meter? I don't
know how thoroughly this antenna bug is going to
bite, so I'm going to limit my search to those SWR
for VHF and UHF, and not spend the extra money for
HF capabilities.

Thanks,

Jim Ek - KB9VEZ
Bloomington, IN

Comparing a yagi or other gain antenna will be like night and day compared to a vertical when aiming to an airport. The only problem is the band is wide, and it will be hard to have the high gain across the whole band. A log periodic could be good. Myself I just use my 2m el yagi that is vertical. It's fairly omni at 120-130 mhz. With the high sensitivity of the 706g on the aircraft band I can hear quite a bit. I'm about 15 or so miles away from one big airport and 25 or so from another. I can hear the towers to both. I can hear the ATIS for both usually. I usually don't hear too many planes on the ground, but that is normal. I might hear a 737 at hobby every once and a while if they taxi in the right direction. Their antennas are in the vert stab, and pretty high. Also they have fairly powerful radios. As far as in flight, I can listen to a southwest 737 take off from Houston Hobby, and follow his flight all the way to Dallas to the point they descend below about 9000 ft into Dallas. Tuning in order would usually be : 118.7-119.7-132.77-132.27-etc. 132.27 being fort worth center, and I lose them on the handoff to approach. Freq's will vary many times. Not too bad for a low gain antenna. I can hear many aircraft that use Forth Worth Center up in north Texas. Using the ACARS decoder, I've tracked planes to about 300 miles out. Nearly to the OK border from Houston. West texas, LA, etc. You don't have to be too high up to get a nearby tower freq usually. Depends on the airport though. It is a large improvement going to most any outdoor antenna compared to a low indoor antenna. The indoor antenna will pick up planes in flight though. Heck, my 2m 1/4 wave GP hanging from the ceiling in this room can hear hobby tower most of the time. But the 2m yagi at 35 ft is much better. I once made a 4 el yagi for 171 mhz to listen to the NASA capcom feed back in the old days. I used to tune around the marine band and listen to boats out in the gulf, and in Galveston Bay. The yagi heard signals out there that didn't exist at all on the ground plane. The same would hold true listening to airport ground chatter and towers. The bummer part is one tower might be on 118.7, and the next on 127.3, etc. Quite a spread...Not to mention the 132-134,etc mhz center freqs. Luckily you don't need the high gain for planes in flight, so you can concentrate the gain for the tower freq's. Most of the unicoms are in the 122.7-8-9 range. Chopper unicom here is 123.025. Very active here in Houston with all the news, police lifeflight, etc.

Dear Jason,

Please don't apologise for your 'green'-ness. Here you will meet many people as green as you are. The problem is how to distinguish the sheep from the goats.

Not having had any practical experience with 118.5 MHz or thereabouts for 57 years I will not offer advice on building your proposed antenna myself. But I will say your approach to the job is truly in the spirit of ham radio - just check on the materials you already have, use your ingenuity and consider what can be done with them. To begin with a ready-made plan and then working your way down a long shopping never works out - it never worked for me - there's always something unobtainable towards the end. Plans are made to be changed.

I like your apt use of "grab" in connection with antennas. It should be entered in the IEEE technical dictionary. (Cecil please note)

Perhaps "more gain" should be replaced with "less loss". Antenna gain, to within 1% of a decibel, is a phrase used by salesmen as a fictional selling point. No antenna can be more than 100% efficient.

Happy constructing. Hope to meet you here again.

This will probably cause an argument - my advice is don't get an SWR meter described as such - get an impedance measuring device. Set off on the right foot!

But if you insist, recent Z-measuring devices have an SWR-indicating scale built in.

SWR meters sold as such do not in fact measure SWR - not even if located at the antenna end of the transmission line.

There's a short article about so-called SWR meters at http://www.g4fgq.com

Trouble with many relays, except mercury-wetted or otherwise designed for the job, is high contact resistance on receive. Sooner or later they start giving trouble if left unused for a few hours.

Short term remedy - transmit full power for 1 second.

At this point I am electrically unsophisticated
and have a meager financial boundary for this
pursuit.

Quick checks of some internet vendors show that
impedance measuring devices are many hundreds of
dollars.

I'm viewing this as an elementary exercise in
antenna experimentation, with an eye on moonbounce
using a 5 watt handheld <grin>. Not a new career.

Please don't forget that lots of people are being "forced" to use
IE thanks to Bill. Lots of people aren't familiar with computers
and other browsers and just use what their computer offers.

If it would be possible to make statistics of browsers which have
been chosen by the users themself, I'm sure Netscape will do better.

By the way, I'm using Netscape 4.71 for quite some time now, and
there are only a few sites that aren't "readable". Some other sites
look a bit better in IE, but this is the first site that really makes a
mess on my screen, and I really browse quite a lot! :)

Bye,

Peter Hunt
Holland.

Jim, sorry my description 'impedance measuring device' led you a little astray.

The MFJ259B is an impedance measuring device up to 170 MHz but earlier you said you didn't like some comments made about MFJ products.

I have an MFJ259B. I'm reasonably happy with it. It does jobs which larger more expensive instruments can't do. It is a power hog and soon flattens its own internal batteries. But I use an external DC supply with an RF choke in the power lead.

It measures Z = R+jX but unfortunately does not indicate the sign of jX. That has to be decided by the user by looking at the antenna and length of feedline and using some mental logic. I don't know whether there's a later version of the instrument or whether there's another manufacturer.

It also measures SWR - or rather it calculates SWR from R+jX. It also usefully measures L, C & R component values in the shack provided you already know what type of component it is.

All an ordinary SWR meter tells you is whether the transmitter is loaded with 50 ohms or not. That's all most people want to know. Furthermore it needs the transmitter to be connected to it before it tells you anything at all. If the transmitter is very low power it may not tell you anything even when it IS connected.

For antenna *experiments* I think you will find a simple SWR meter is not enough. You will often be working in the dark. If you go ahead and buy one make sure it works at the power levels you intend to use. There are a variety of manufacturers including those in the Far East. I would think second-hand meters are readily available.

You have to know that ole Charles not only advocates eQSL as the only creed,
but also is a disciple of the Church of Micro$oft. Whatever this great
American company produces, simply *must* be great.

Computer security is an area that this gentleman knows nothing about. But
that's good, since he's one of the guys that produces an infinite stream of
money to security consulting companies. It's people like ole Charles who
promote the fierce growth of security tools like virus walls, virus
scanners, firewalls, trojan scanner etc.

Cecil,

Thanks for the relay info. I was one of the ones inquiring as to the feasibility of their use. I am debating among several antennas to use at my location. When I saw your no tune antenna plans, I added your design to my list.

I'm leaning towards either a trap or loaded dipole for now. I am limited on space, which would make it nearly impossible to erect a 130' dipole without bending the ends at least 25' vertically. I wonder if your design would tolerate using loading coils, with the center frequency set at 3.7 Mhz, and still allow all band operation? The shortened dipole would be about 80' long. Even better for my lot would be loading and bending the antenna as an inverted V.

I would want to avoid relays, but I don't really have a decent location to mount the manual switch network without interference to the ladder line. At my location, relays would have to be used.

I've read that antennas of similar design generate higher than normal harmonics. Do you have harmonics and what steps do you take to curtail them?

Thanks,
AB

Hi Jason,
Your ground plane should be resonant, or pretty close to it, so you
don't need to cut the coax to a certain length. At one time I had a
ground plane up on a mast made from 2x2's, and it had pretty good
coverage (contacts up to 75 miles during a 2 meter contest). If you
can't add a mast to your place, see if you can get a rope high up in a
tree, tie the rope to the vertical on the ground plane, and hoist it
up. You might want to get less lossy coax like RG-8 or RG-8X to
decrease the line loss when you increase the length of the line. 73 es

>>The bummer part is one tower might be on 118.7, and the next on 127.3, etc. Quite a spread...Not to mention the 132-134,etc
mhz center freqs....<<

That's the flip side of the coin. While I get good gain performance and a decent match over a 10-12 MHz segment of the band with the 8-element Yagi, its pattern falls apart pretty fast after that. A LPDA could provide full-band coverage with a bit less gain. LB Cebik's recent work is probably good resource for designing an airband log. When it comes to antennas, there ain't no free lunch.

>Luckily you don't need the high gain for planes in flight<

At times, high gain is a liability for monitoring planes in flight. My Standard C-108A HT has an incredibly hot front-end in the airband (<.3 uV for 10-dB s/n), but blocks on strong signals when connected to the yagi. Fortunately, my desk-top scanner has better dynamic range.

From: Marvin Born <mborn@k8xu.com>
Message-ID: <3C78F8F7.E595F511@k8xu.com>
Source record: 147929

There is not a simple answer, but

TV signals are normally horz. In the 1940's all were horz., they are never only vertical. However, many years ago many stations stared to add a vertical component with power equal to the horz but 90 degrees out of phase. This made it circular, which was to help with ghost reduction. Even later stations only added 20% vertical, because the high vertical component caused its own form of reflections, CP receive antennas could only be channel specific and people wanted multi channel receive antennas. Also the additonal power ran up the electric bill and tube costs.

The vertical component is more common to VHF stations than UHF due to the power requirements at UHF.

Hope this helps.

Hello Walt,
The minimum screen size I test for is 800x600. If your screen is
smaller than that - or - you have additional menus or browser add-ons,
or ISP ads on the side, that claim part of that space you may have to
use the horizontal scrollbars.
BTW whichever browser one uses has nothing at all to do with the
screen size. That is a Windows function setup in Display / Properties

I have a Bendix -King LPU-4991 UHF HT.
The 1/4 wave whip has broken off where the flexible part of the antenna connects to the connector fixture that screws into the HT case.
It looks similar to the antenna connector used by Motorola on HT-220's. I think they may be called 1/4-20 connectors, but I am not sure.

I am looking for two antennas:
One 1/4 wave whip,
and one "stubby" helically wound antenna.

If you have either of these items for sale please e-mail to:
aga4fl@yahoo.com

TIA

Quickie 118.5 MHz sidemount:

1. Take two 24" rods (brass welding or aluminum) and tread one end of each. For a boom, take a 15" length of plastic pipe.

2. Drill opposing clearence holes at one end of the pipe and install the two rods dipole style, securing with nuts. Drill holes for--and Install--a U-bolt/mast clamp at the opposite end 90-degrees offset from the dipole.

3. Take a length of RG-8M, make 1-1/2" pigtails at one end and install spade lugs. Connect this feedline to the dipole, securing pigtail lugs under the elelment nuts.

Side mount this antenna on an existing antenna mast with the dipole facing in the direction of the airport you want to receive. The mast will act as a reflector and the spacing should be about right for a 50-ohm match.

Alternatively, if you're really fanatical, make a second identical dipole, connect 78" of foam 75-ohm coax to each antenna (TFE insulation Vf = .78), splice the free ends of the 75-ohm feedlines together at your 50-ohm line inside a 35mm plastic film can or pill bottle, and mount the antennas with their booms about 95 inches apart. Voila--instant 5-dB collinear.

"David or Jo Anne Ryeburn"
> *Exceptions: 9 year old versions of Word and Excel,
> both so ancient they are ignorant of macros, and thus
> immune to macro viruses.

MS-Word 2000 (even the included-with-most-PCs SR-1 version) can be set to disable unsigned, untrusted macros. The option is under Tools, Macro, Security, High or Medium.

Of course, anyone that is concerned with security and viruses would have Norton AntiVirus 2002 (or equivalent) running and keep it (and everything else) up to date. It will also eliminate the threat without throwing the baby out with the bathwater.

Crume's book 'Inside Internet Security' advises that it is generally more secure to be up to date than to be on the trailing edge. Generally more old holes are being closed than new holes created. And the new holes are generally less well known. Good book.

Let me repeat - I see both approaches.

At my workplace they run Win 95 on the desktops and Win 2000 on the servers. The went cheap and use McAfee junk for AV. The place is a Help Desk disaster area. Blue Screens of Death left, right and centre on a daily basis. Even had a big virus mess a few months ago (things not up to date). Stupid.

At home (having seen the mess at work) I try to take the opposite approach and generally keep things up to date. Try to get the latest SW on sale (XP Cdn$99) or with a fat rebate (Norton 2002 Cdn$30). Never looked back. When we get a virus by e-mail , Norton pops up and offers to nuke it. Stable as all get out. Close to a perfect PC experience.

Of course, everyone is free to choose their own path through life. Best wishes.

My method works for any 450 ohm SWR between 4.5:1 and 18:1. That's quite
a range but some antennas are out of that range including very short
antennas.

> I've read that antennas of similar design generate higher than normal
> harmonics.

My antenna is resonant on only one frequency at a time and therefore
attenuates harmonics. But linear antennas cannot *generate* harmonics.
If the transmitter is clean, a linear antenna will be clean.

Daiwa makes good cross-needle swr meters. They have a vhf version. AES has them.

I use a Bird 43, and it does a decent job, but it's a little pricey compared to
others.

Reg is right, you may want to know more than just the swr, but as far as
measuring swr goes, there are plenty of good meters for that.

Don't use any Micro$oft products and be rid of all those problems mentioned above. I f you decide to use Non-Microsoft products for any internet-based applications, your risk of running a compromised machines is reduced to an amazing extent.

All severe security holes related to trojan horses and viruses are Microsoft security holes. What does that tell us? I don't run a firewall, virus wall, trojan horse scanner or other crufty pieces of software and yet my system is secure. Wanna bet?

If you learn to use Microsoft you end up with the same results.

> *All* severe security holes related to trojan horses and viruses are
> Microsoft security holes. What does that tell us? I don't run a firewall,
> virus wall, trojan horse scanner or other crufty pieces of software and yet
> my system is secure. Wanna bet?

So Peter doesn't run MS products due to its security issues. I suspect Peter walks (only when streets are deserted) and won't use motor vehicles because they are involved in so many accidents. Peter must not fly, airplanes are related to most air fatalities. No boats, you could drown. No sex, STDs and heart attacks. Peter should pull the plug on his computer, fire hazard!

MS products ROCK if you know how to use them. Oh, you wouldn't know, you don't. To each his own.

Reg Edwards wrote:
"Perhaps "more gain" should be replaced with less loss."

Gain should not be confused with loss.

I am going to drive Reg up the wall again by quoting Terman:

"Directive gain depends entirely on the distribution in space of the RADIATED power (Terman`s emphasis, not mine). The power input to the antenna, the antenna LOSSES, (emphasis mine, not Terman`s) or the power consumed in a terminating resistance have nothing to do with DIRECTIVE gain (Terman`s emphasis, not mine). Such factors are taken into account in terms of the POWER gain of the antenna which is defined as the ratio of the power INPUT that must be delivered to the directional antenna to obtain the same field strength in the same direction. Unless otherwise specified the comparison antenna is a LOSSLESS isotropic radiator."

Terman says there are two gain figures, the directive gain figure, and the the power gain figure. The directive gain does not include loss. The power gain takes loss into consideration. We get ERP from power gain, not from lossless directional gain. I`d wager that is what Reg intended in his statement which should not be taken the wrong way.

Power gain is just the power in an isotropic versus the power in a gain antenna to produce the same signal at a distant point in the same direction. It does include loss in the gain antenna as Reg said.

Terman`s definitions above can be found starting on page 870 of the 1955 edition of "Electronic and Radio Engineering".

I would discuss the scripture quoted above but not add to nor subtract from it except for the said capitalization of LOSSES, for purposes of emphasis and illustration.

A ground plane antenna has directional gain versus an isotropic antenna. The ground plane probably has a power gain over an isotropic antenna, but could have enough loss to nullify its directional gain.

Best regards, Richard Harrison, KB5WZI

>Since aircraft COM antenna standards require VERTICAL polarization, I'm presuming both of you gentlemen have VERTICALLY polarized gain antennas, yes?<

Geeez, Jim! Your question does, however, raise the issue of decoupling a single vertically polarized Yagi from its mast and feedline.

For the 12-foot yagi, the top 5-feet of the mast is non-conductive fiberglass (painter's pole), and my feedline drops down at the mast mid-way between elements with four #43 ferrite sleeves spaced along the first 3 feet of the drop. I was a little skeptical of doing it this way, but according to the analyzer, SWR was virtually unimpacted by the feedline drop when I installed the sleeves as described. Take 'em off, and it's whole different story!

I did get lost walking home from the bar the other night. I forgot to hold my IC-A23 on its side, and the CDI wouldn't work.

Fellows, pardon a lurker squeaking up.

I agree with Reg, the number a "SWR" meter will give you is limited in usefulness. You don't mention what other test equipment you have. A signal generator, a 'scope and a reflectometer built from the the plans in the ARRL antenna book will give more information than you can get by firing up a transmitter and reading a number off a meter. Of course the equipment will have other applications in the shop.

Use an SWR meter with my ladder-line length selector and it is amazing
what information it yields to the initiated. If a parallel cap and
increasing the frequency slightly doesn't yield an SWR of 1:1, the
impedance at resonance was higher than 50 ohms. :-)

[x] Crosspost and follow up to news.admin.net-abuse.usenet

Your provider has been notified about your constant abuse of usenet.
Constantly crossposting as default behaviour of your news-client is
unacceptable behaviour by usenet standards. This is clearly stated in your
provider's terms of use, which can be read here:

http://www.bnb-lp.com/terms_of_service.html

Explicitly the following two paragraphs should make things rather clear to
you:

"Sending a message to many different off-topic newsgroups (Cross Posting),
is particularly unacceptable and will be treated as inappropriate posting
which may result in account suspension or cancellation.. You agree to abide
by BnB's policies concerning use of BnB's Internet Services. BnB reserves
the right to suspend access to service for your account(s) upon an
indication of disallowed use."

and

"You agree to pay a fine of $500 for flagrant disregard of allowable use
policies including sending unsolicited commercial email, spam, or via
posting commercial messages to Usenet discussion groups whose charter does
not explicitly allow advertisements. You also agree to reimburse BnB for any
costs involved in dealing with such incidents. BnB staff time will be billed
at $ 50.00 per hour. It is at BnB's sole discretion what constitutes such
flagrant disregard of allowable use."

A formal complaint has already been filed with abuse@bnb-lp.com.

> Cecil, it is not the SWR meter which tells you anything - it is the
> parallel capacitor and the increase in frequency.

Reg, my SWR meter tells me more than my MFJ-259B. For instance, the SWR meter reads 2:1 at system resonance. We know we are looking at either 25 ohms or 100 ohms. Hang a parallel capacitor at the match point and increase the frequency slightly. If the SWR goes down, we are looking at less than 50 ohms. If the SWR goes up, we are looking at more than 50 ohms. And not only do I know the resistance, I also know the sign and magnitude of the reactance by knowing where I am on the Smith Chart. The admonition, "Work Smarter, Not Harder!", comes to mind.

Note that the SWR meter is the only 'input', i.e. the only reading. Everything else, including the capacitor, is an 'output'. This is the kind of Rube-Goldberg thing that hams have been famous for. I also have a 'Ladder-Lizard' that I can slide up and down the ladder-line to locate the current-maximum/voltage-minimum points and the current-minimum/voltage-maximum points. I'm talking cheap stuff here. Anyone who wants a 'Ladder-Lizard' for $10, send me an email. It works with magnetic toroidal pickups to give one a DC voltage reading. My CA pardner developed liver cancer and left me holding a bunch of useful stuff.

Richard,
What loss are you referring to here? At the frequency that he is interested in, any practical ground plane should be far enough from the surface that any ground effects should be negligible. 73,

Excellent suggestion. With Lechter wires, a diode and a meter he
wouldn't need an SWR meter. There are a lot of ways to skin a cat.

On building antennas for the neophyte. If I am going to be following 'well established' plans for building a J-pole, or Yagi. An SWR meter will give me a sufficient reading to tell me that using the antenna that I construct, won't burn up my HT, correct?

Then maybe a couple of months down the line purchase a field strength meter, which will confirm why I'm not able to hit the repeater in the next block, with the antenna I built <sick grin>.

Later still, if I decide that antenna experimentation with some of my own creations is something that I want to pursue. Then I should be looking at acquiring more sophisticated equipment for impedance measurement, and signal generation.

Or am I just completely on the wrong page and need impedance measuring capabilities from the start?

SWR meter is a form of impedance measuring device. It just takes longer to sweep the frequencies of interest.

Field strength is not of much use except to know that your rig is transmitting something. And SWR meter forward power into a matched antenna does that too.

Aloha,
John KH7T

Here are a few ways you ruffle:

One, we end up with subject matter unrelated to a particular group's reason for being. Such posts come out of the blue, and simply confuse.

Secondly, it clutters up the groups with superfluous headers and messages.

Third, it ticks people off.

Fourth, you end up insulting people.

And fifth, you already irritate people enough, with constant spamming for your website.

So, if you want to come off as a doofus, you're doing that fine.

And you're doing it all over Usenet.

Have a good day.

Hello Zoran,
Sorry but I have no pot to sell you. If I - did - have some I would be willing to share with you for free.

The idea of cross-posting IMHO is misunderstood by many. It is a very effective way to disseminate information while only needing to compose a single message. I have to disagree that cross-posting is never "justified". That is just your opinion.....

Some people when they see any message at all that is either not to their liking for content - or - posted to more than 1 newsgroup immediately put on their Spam Cop / Cross-Posting Marshall hats and lead a one-person crusade against the perceived "offender" Many times reply-after-reply get repeatedly cross-posted because the original addressed groups never get edited.....so at one time or another almost all Usenet users are "guilty" of the dreaded scourge of "cross-posting" and many do not even realize it.

Bob Dylan said it best I think..
" ....and don't criticize what you can't understand"

Now this is not directed at you Zoran personally..but at those type of people I have just mentioned

Hi Jim,

You are doing OK (to ignore those who babble on).

When push comes to shove, its not the equipment, its the user (much like the admonition of the poor carpenter blaming his tools). Cecil has offered several means to accomplish all that you seek without spending more than $25 and THAT is the bottom line (you can even do better by finding one at a swap meet). The fact is, you could end up paying more to build it by parts from scratch (which is not a bad idea, in and of itself).

Don't fall for the analyzer trap that drains your wallet only to give you marginal answers, or more cash for more digits of noise. A digital readout is no more accurate than a 1" meter they replace. For some, the digital watch is the height of civilization. Skip the fanciful discussion of obtaining the sign of the reactance - it isn't worth the cash outlay for something so simply determined within a minute of use (already discussed by Cecil). Also ignore the academic discussion of "you aren't actually measuring SWR" (or fill in the fanciful equivalent for SWR). Another troll that surfaces too regularly.

Also skip the discussion of quality of construction or actual accuracy. These are things you can determine and correct for yourself without too much grief (and are NOT guaranteed for the premium analyzers touted here). For instance, you might mistakenly pick up a VHF/UHF SWR indicator that simply looks broke at HF. This is a sensitivity problem, nothing more. It only demands a resistor change or the use of an external meter (something that you should have in your shack, not something you should buy solely to fix your mistake however).

You can calibrate your meter yourself using known loads (resistors that can support the power applied long enough to note a reading). In this regard, you can make your own calibrated scales to replace the original (but this too will be unlikely).

Without shopping for the benchtop network analyzers, every SWR meter you consider will have the same design (and even so those premium analyzers touted here). There will be variations between them, but these will be insubstantial, amounting to a cap or a resistor (something you can buy for replacement, but that too is unlikely required).

You might be tempted to buy a cheap meter and gut it to rebuild it with precision components and quality methods. Even there, you are not likely to improve on something that was in all likelihood working quite well. However, this is the better philosophy (short of arbitrary gutting that is). In other words, a cheap Radio Shack SWR meter for CB use could be pressed into general service. It may exhibit some problems already discussed, but guess what? That $300 analyzer could do worse. One of my SWR meters is from Radio Shack and it exhibits rather marginal metering, but the sensor head is very well designed (and is the part that really matters).

In other words, consider it a project, not a purchase. Test it for general application (is it sensitive enough?). Test it for balance (reverse the input/output and check for null readings into a 50 Ohm load). Test it for accuracy (using 25 and 100 Ohm non-inductive resistors - other values too if you wish). Correct those tests that fail or do not perform well (easily within the scope of the meter and your talent - if you know which end of the soldering iron to pick up ;-)

wrote:

Paul;

|I am not trying to talk you in to upgrading your software or your processor.

Where I live the best I can get is a 28.8K dialup connection. (No cable, no DSL, no Sprint) No amount of processor upgrade (I have a PIII-450) or software "upgrades" will do a damned thing about increasing web throughput.

I have already stated that I am not an on-line buyer, however, I *am* an on-line shopper. I am also manage three IRAs on-line. So I have had similar discussions with the tech people at Charles Schwab. I have pointedly told them that if they wish to keep my business then they should stop demanding that I continually upgrade to the latest browser and Java everytime one of their web page designers gets a new wild hair up you know where and wants to add a "feature" to their site that requires me to spend a couple of hours on Microsoft's site updating my Java. (They tried to get me to do this so I could look at one PDF format analysist's report.)

In my last telephone call I pointed out that I can (using my "obsolete" Netscape Communicator 4.5) go to Yahoo Finance and download in CSV form, a list of my holdings, their prices, historical data, etc, and import it directly into my Excel spreadsheet where I track such things. Furthermore, this is free. If I want similar history data from Schwab, I get an HTML form, that can take minutes to download and format and then there is nothing I can do with it other than print it out which takes a few more minutes. They have agreed to "look into this."

In my opinion, and I told them so, their web page designers should have to design their page, send it to a server via a 28.8K connection and then download it back to their browser the same way and see if it works.

Web designers do things for the same reason mountain climbers climb mountains, because they are there and it can be done. If they don't keep changing things, they're out of a job. Sort of like lawmakers, if they don't keep coming up with new lamebrained legislation, they might as well go home and give us a rest. For both groups that would be a good idea.

|You might find this interesting, however. I asked a company which is a
|fairly major vendor of out-sourced web design why they ignored older
|browsers. The answer was that folks with older browsers tend to NOT be
|on-line buyers (they gave me some comparative statistics which I do not
|remember and never knew from whence they came). If this is true and the
|purpose of the site is to sell stuff (as opposed to merely increasing hits),
|then ignoring older browsers might well make business sense.

I'll tell you what. My son is the IT manager for a vehicle rental company that has offices nationwide and does over 50% of its business with foreign visitors to the US. I know for a fact that I can fully utilize his site with my "obsolete" browser. I'll talk to him and ask whether they are willing to pass up business that might be from people that don't use the latest version of IE.

Regards,

Wes

Bill Klocko, N3WK wrote:
"What loss are you referring to here?"

I completely agree with Bill that:
"At the frequency that he is interested in, any practical ground plane should be far enough from the surface that any ground effects should be negligible."

Line of sight antennas must be elevated to 'make the trip" of any great distance. Terman`s definitions which I quoted were for "directional gain","power gain", and losses. These were general for any type of antenna so I wasted bandwidth with a comment that: "The ground plane probably has a power gain over an isotropic antenna, but could have enough loss to nullify its directional gain."

I wanted to be general too and was thinking of an antenna close to the ground losing energy from the displacement current in its return through the earth to the antenna drivepoint. Agreed this is an impractical situation in most cases at VHF and higher frequencies.

Best regards, Richard Harrison, KB5WZI

Hi Pete, I've got a little demo for an CW generator that I was working on a few months ago. It's just a demo, but you might find it useful. I gave up on it because I had other priorities. It only does a line's worth of text, but if it looks like it might suit your needs, let me know and I'll fix it so you can paste multiple lines into it. You can download the demo at:

http://www.netdave.com/wa0ttn/demos/cwtest.zip

If you're interested in PSK31 software, or my other feats of daring do :-), you can visit my other ham pages at:

http://www.netdave.com/wa0ttn

No uplink ???? Click on "-How it works". You can use your dialup modem
for the "uplink", or get the 2-way DirectPC.

"Gary - KJ6Q"
> 3. Pay considerably MORE than the $19.95
> You weren't really paying attention, were you!

Calm down. Wes *did* imply a desire for DSL or Cable and seemed to think
that there was no other option. DirectPC is in *roughly* the same ballpark
as those other "land locked" hi-speed providers. The set-up cost for
DirectPC might be steeper, but the monthly cost is the real long term cost
anyway. There is a delta (obviously), but it isn't huge (compared to DSL or
Cable).

The only "stiffer" requirement might be a USB port (assuming his PC isn't
too stale). That's a $20 problem.

I'll probably be using the Canadian equivalent to DirectPC in a couple of
years.

I find the late shift seems to do better to EU for 80/40m. You can
begin to work EU or Africa when it gets dark local time, but I find
this a bad time usually. But the first shot is usually ok to Africa. I
find if I wait until the sun is almost up in EU, and about midnight
here, I do better. I start looking for Pacific about 3-4 AM local. I
work the VK's and JA's early in the morning after EU is pretty much
out of the pix. EU on 40m is quite easy. Just get on at midnight,
about 7028 +,- and listen around. One will usually pop up before too
long. I don't really work much dx on 75m, but I do hear quite a bit
down in the window when the band is quiet. Also in the low end
3500-3550. MK

Windows XP is full of security holes - as well as having many other
problems.

As far as browsers - Internet Explorer 4.x is more troublefree than
the new IE 6.x software - which also is loaded with security holes.

> to deal with billing errors or bogus charges.

Sure there is - you call the phone company up and tell them to remove the
charges/errors. If they don't, you just find a new company - there is plenty
of competition out there.

Telling a person they need to use the latest internet browser is like
telling a long time unix user that he cannot use tin as a newsgroup
reader - but will have to use MS's latest browser instead. That is the
same as telling the people that they must use virus/worm susceptable
software - just so the web designer can show of his/her latest whiz-bang
byte/time/cpu hungry trash.

Sorry, Charlie. If I cannot read a site with the old browser I have, then
I won't visit the site again. There are plenty of others that are just as
good.

Well, they are wrong about some of us. I spent over $40,000 online last
year. A close friend spent over $15000. Both of us use old browsers, and
are not about to upgrade.

None of my friends have IE 6x, nor do they plan on getting it.

It is only the people who just MUST have the latest and greatest that
upgrade or buy new machines. The vast majority of consumer PCs are old
Pentiums with minimal RAM and the same software that came with it.

Norton AV can only catch viruses after they have been out long enough to
be captured and analyzed - then a patch created. In the meantime, thousands
of PCs catch the bugs - and often don't know that they are there.

It, just like any other AV software, works "after the fact". It can only
prevent you against future occurances of the same attack.

And if you don't have the capability to scan all incoming files etc before
they are opened, then you are still vulnerable.

> Crume's book 'Inside Internet Security' advises that it is generally more

> generally less well known. Good book.

This is true for software/firmware that has been around for a while. It is
NOT true for relatively new releases. IE 6.x is still in diapers. It will
need many "fixes" before its holes are plugged as well as those in IE 4.x

You forgot the bit about sealing the coax at the place where the center
conductor is pulled through the braid.

The antenna/coax will not work well for very long, without doing so.

But it does not tell you the resonant frequency of the antenna. All it
tells you is when the antenna is closest to a 50 ohms impedance.

> Field strength is not of much use except to know that your rig is
> transmitting something. And SWR meter forward power into a matched
> antenna does that too.

Connect that SWR meter in front of a dummy load. You are not radiating
very little RF, the rest as heat. This tells us little about the usefulness
of the antenna. That is where a field strength meter is useful.

you only need one method of measuring the feed point impedance of an antenna. an swr meter is the easiest(though it doesn't measure impedance) , impedance bridges, 'analyzers', etc just give you more detail but aren't that useful unless you really understand what they are showing you. and none of them give you any idea about the antenna pattern, only about how close the impedance of the feed point is to your coax.

a field strength meter can help you determine an antenna pattern, though doing that right is much harder than it sounds.

At minimum SWR, you are at a current maximum point. The SWR gives
one of two values of resistance. A parallel cap will tell you
which of those two values of resistance is true. Knowing the
length and characteristics of the transmission line will yield
the antenna feedpoint impedance as an indirect measurement.

Wrong (at least 80% wrong ?). From the Norton AntiVirus 2002 Help file for your education:

"All computer viruses fall into two groups:

Known viruses: <snip>

Unknown viruses: An unknown virus is one that does not yet have a virus definition. Norton AntiVirus includes an advanced heuristic technology called Bloodhound to detect unknown program and macro viruses. Bloodhound isolates and locates the various logical regions of a file and then analyzes the program logic for virus-like behavior. Bloodhound detects a very high percentage of unknown viruses. In addition, Norton AntiVirus detects unknown viruses by monitoring activity on your computer for behaviors that viruses typically perform. When a suspicious activity is detected, Norton AntiVirus prevents the action.

Copyright© 2000-2001 Symantec Corporation. All rights reserved." Fair Use - education.

> And if you don't have the capability to scan all incoming files etc
> before they are opened, then you are still vulnerable.

Wrong. That feature is called 'Autoprotect' and it is recommended that it be left in its default setting, ON. That is exactly what it does.

3914. Radiating pattern for vertical delta loop

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-25 13:48:01 UTC
From: Larry Gauthier <larryg5099@chartermi.net>
Message-ID: <u7kg4pdjh1t672@corp.supernews.com>
Source record: 147902

Following some advice from folks on this reflector, I built a full-wave vertical delta loop for 30 meters, and it works great (by simple comparison to a dipole which is actually higher). The antenna is fed with an RG6 1/4 wave balun, and is built as an equilateral triangle (all sides same length). For vertical polarity, the driven side is perfectly vertical (held at its apex by the tower), with the feed point 1/4 wavelength down from the apex. The other two sides form a horizontal arrow that is pointed South.

Because this antenna "points" in one direction, I wonder if it has some directional characteristics. Perhaps I could aim it in a specific direction or put up a second one that favors Europe or Asia? Unfortunately, my collection of antenna books does not cover vertical loops. I tried modeling it in EZNEC but still do not understand EZNEC well enough to model anything but simple dipoles. <sigh>

What are the propagation characteristics for a vertical delta loop? Has anyone modeled one of these antennas? Thanks in advance for your responses,

-larry

Hi Jim:

I can't help with the EZNEC questions, but the people at "GAP" tell me, the coax with the capacitor can be looked at as an inductor. As for why its inside the tubing, it is just a good place to put out of the way.

You're on the right track. Just buy an swr meter that measures your vhf frequencies. There are many good brands. The ones MFJ makes work fine. I have one on my antenna tuner, and it does a good job.

If you're getting one to measure the output on your ht, make sure it has a scale that will give you a measurement at the 5 watt-or-so level. In other words, if the scale is for, say, 0 to 200 watts, you may not get enough deflection to get an accurate reading.

Other than that, you can look at what is available at the MFJ web site, or just call AES or HRO or Texas Towers or whomever and see what they have in stock.

Later, when you get more advanced, you may want to move up to the antenna anylyzer that MFJ makes, the 259B, but for now, a basic swr meter will make you good to go for your antenna experimentation.

Thanks for all who replied, but after some thought I have decided to stay with the pole and guy wires.
If anyone is interested the tower is now for sale..

Approx 26ft triangular cut into two sections , but will be easy to sleeve and weld.
Best offer
Buyer to collect.
Geelong Victoria

Cheers all
Andre

Larry,
The 'normal' direction of radiation for a vertical
loop (no matter the shape) is broadside to the loop.
There's usually a 'null' in the sides in the plane of
the loop. This isn't 'set in stone', though. Depending
on what's around the antenna, the radiation pattern can
be skewed so that you really can't predict exactly where
it's 'pointing'. It sounds like your antenna should
'hear' best East and West. Does that 'fit' what your
'seeing'?
'Doc

Larry, K8UT wrote:
"Unfortunately, my collection of antenna books does not cover vertical loops."

Delta loops are covered in chapter 10 of "Low-Band DXing" by ON4UN, published by ARRL. Borrow a copy.

Figure 10-9 shows an antenna more or less like Larry`s. "The delta loop can be seen as two quarter-wave sloping verticals, each using one radial."

Figure 10-10 shows radiation patterns. In the horizontal plane, the pattern is slightly oval but is almost omnidirectional. In the vertical plane, of course, the angle of maximum radiation depends on height of the antenna.

Best regards, Richard Harrison, KB5WZI

Source record: 147908

Doc,

Yes, that seems to be what I am hearing. But again, my only comparison is vs the dipole, and the loop beats the dipole in every direction. My only clear example was the TI9M DXpedition, which is broadside to my dipole and off the end of this loop. But, the loop was better there as well even though the dipole is higher (of course, there is probably some vertical take-off angle benefit from the vertical polarity of the loop.)

I did not know if the "arrow" (the two legs that point south) would give this some preference to south versus north, which might have explained why the TI9M signals, due south of me, were so good. Also, the tower is 4 feet behind the loop, to the north of it, so I have a natural null going over the pole.

If this is bi-modal as you say (favoring the sides and not the front vs back) then I will put up another one and place it at 90 degrees to this one. I would expect to see better signals into Europe/Africa and the Pacific rim from this loop, and better South Americans with the new loop. Even as it is, I'm having a great time working 30m DX with the one I have.

Thanks for the response,

-larry

On it's resonant frequency, the major figure-8 lobes are broadside
to the vertical loop, somewhat like a dipole (but not identical).

If you're not able to hit the repeater in the next block you have something more than an antenna problem, you may have a direct short circuit in your feedline. Almost
any RF radiated at all would accomplish that. Check your coax connectors, they are
a usual source of short circuits if whoever installed them was not experienced.

I didn't forget it at all. This little design was a one-shot to see if anything was above the noise floor. It wasn't intended to be anything more than a one-week test at the most, and not much deterioration is going to happen in a week. When he proves or disproves that a simple outside antenna is going to do him some good, then we can talk about some serious permanent antenna designs.

Not really. All FAA ground stations use a combination of vertical and horizontal polarization just to eliminate the effect that you are talking about, with the aircraft in something other than straight and level flight. Only in the smaller airports (unicom and such) will you find true vertical polarization. However, in trying to listen to an airplane on the ground, you will find predominantly vertical polarization -- unless, of course, it is a taildragger in a ground loop {;-)

3930. Stainless steel tubing for elements & boom for UHF antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-25 18:59:52 UTC
From: joe <casavant@nucleus.com>
Message-ID: <3c7a7cd2@news.nucleus.com>
Source record: 147917

Hello,
I work in Varadaro, Cuba, and wish to make an UHF Yagi antenna to receive FOX ch. 29 from Miami, 100 miles away . I have a 30 db booster and coaxil which I brought from Radio Shack in Canada. The biggest problem I and having is making the antenna because all of the antenna designs call for aluminum tubing and I can not find any aluminum in Cuba. However, because of where I work at, I have access to loads of stainless steel tubing ranging from 1/4" to 2 " and a small amount of 1\4" and 1 " copper.
My Questions are:
1) Can I use Stainless steel for the Elements?
2) Can the boom be made of conductive material like stainless?
3) Any designs to get the best signal strength?

I'm not a hobbiest so less technical information is appreciated. Also, this antenna is illegal in Cuba so it should not be more than 10' long.
Thankyou
Andre

> 1) Can I use Stainless steel for the Elements?

Yes. Aluminum has been used because its cheaper, but some of the more
expensive antennas use stainless steel.

> 2) Can the boom be made of conductive material like stainless?

It depends on the type of antenna, but typically, yes.

> 3) Any designs to get the best signal strength?
>

Tough question. Receiving a UHF signal that is 100 miles away with an
antenna only 10 feet long is going to be tough. You will want to use a
Yagi, for sure. A Log will produce less gain although it has better
bandwidth. Keep the preamp as close to the feed of the antenna as possible.
This will give you the best possible C/N.

Jean Claude, VE2UN wrote:
"Sombody have a scheme for a 1.2 GHz yagi or cross yagi?"

You can scale a yagi of one frequency for another frequency and the performance will be the same for both antennas. Mechanically, things get better as size is scaled down. The antenna gets stiffer and stronger at the smaller size of the higher frequency.

Most amateur handbooks have yagis of some frequency which can be scaled to another frequency.

L. B. Cebik, W4RNL has yagi information and more on his webpages. Just search on : cebik.
W4RNL`s pages should be the first items to appear. Cebik has a 3-element example worked out with most details and several options.

3946. Roof Mounted Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-26 01:36:45 UTC
From: Ace_On_Par3 <pwhelton@hal-pcNOSPAM.org>
Message-ID: <a5ep00$1u9a$1@news.hal-pc.org>
Source record: 147783

I'm in the planning stages of putting up a vertical and had planned on ground mounting it with radials and coax buried. I had abandoned the idea of roof mounting the vertical but it seems the more input I get there seems to be some strong opinion that better results might be obtained with roof mounting. So here are my questions:

1. The instructions for roof mounting call for a 45 degree droop angle below horizontal. How critical is this angle? I might be able to handle a shallower angle.

2. Equal length radials should be opposite each other. Can I cheat a little here? Run them any way I can fit them?

3. Given a choice of roof mounting with a maximum of 2 radials per band (10-80) "or" ground mounted with 4 or more 1/8 wave radials per band (10-80) which would you choose and why?

Thanks for your input.

Source record: 147784

Ace,
The 'angle of the dangle' isn't super critical, but the
closer you can get to the recomended angle the 'better' off
you are. It really depends on what you find the input impedance
of the antenna in ~that~ location to be. Just have to try
it and see.
To keep the radiation pattern symetrical, the radials should
also be symetrical. You can stand a fairly asymetrical radiation
pattern with very little 'hearable' change from the 'ideal', so
a little creative 'cheating' doesn't seem too out of order. It
isn't like you need to lay these things out to the exact degree.
Do what you need to do to make them 'fit'.
Given the choice between roof mounting or ground mounting,
I'd
take the one that puts the antenna as much in the 'clear' as
possible.
I also do NOT like heights, especially roofs with a slope like a
ski jump, so that would have a lot to do with it for ~me~. I've
used
verticl antennas in both places, and I couldn't tell any
difference,
same antenna too, so that wasn't a factor. As far as the number
and
length of radials, you can get an argument about the 1/4 vs.
shorter
radials. I tend to favor the 'shorter and more of them' school
of
though (mainly cuz' I don't have a lot of room for the longer
radials).
You know, nothing says you can't change things if you're not
satisfied with how things are working, in fact that's half the
fun of
playing with antennas. Pick a location and design and try it.
Then
change it to see what happens...

wrote:

|Hi,
|
|Does anybody know of a good source for coming up with the right
|dimensions for a hairpin match given the frequency and complex feedpoint
|impedance of the antenna? Books, software, website? Anything?

The hairpin match assumes that the real part of the feedpoint impedance is lower
than the line Zo. The element length is shortened to provide a capacitive
reactance in series with the real part.

An L network is then formed by adding a parallel inductance. So the usual
formulas for designing L networks apply for calculating the required reactances.

The inductive reactance can be provided by a lumped inductor or in the hairpin
case by a shorted stub. The reactance of a shorted stub shorter than 1/4
wavelength is given by:

Xl = Zo * j tan(L)

where L is the length in electrical degrees.

So for example assume a feedpoint resistance = 24 ohm and a line Zo = 50.

The matching Q = sqrt(50/24 - 1) = 1.041

Xc = 1.041 * 24 ~ -j25

Xp = 50 / 1.041 ~ +j48

So you need to shorten the driven element to provide a feedpoint

Z = 24 - j25

and select a stub Zs and length to provide + j48.

Use Zs = 150 ohm

Then: Len_stub ~ 41" for F = 14.175 MHz

These numbers happen to be for my HB 3 element 20 meter beam (made with material
salvaged from a TH-6DXX), viewable at:

http://users.triconet.org/wesandlinda

I don't have links to them but detailed photos of the stub are at:

http://users.triconet.org/wesandlinda/YagiFeed-1a.jpg

and

http://users.triconet.org/wesandlinda/YagiFeed-2a.jpg

In this case, the stub also performs the balun function without additional loss or windload.

There of course any number of combinations that will provide this so mechanical considerations will likely dictate your selection. Also when shortening the driven element the real part will be affected somewhat, so there might be some interation required.

This is all well covered in the ARRL Antenna Book.

Joe wrote:
"I work in Varadaro, Cuba and wish to make an UHF yagi antenna to receive Fox ch 29 from Miami, 100 miles away."

Cuba is out of sight of Miami, but tropo bending, scattering, temperature inversions, etc. can permit occasional reception of Florida TV in Cuba.

Channel-29 occupies 560 MHZ to 566 MHz. Atmospheric noise is very low at frequencies this high, but the signal is very low too. The tiny signal must compete with internal noise of the 30-db booster from the Canadian Radio Shack, in this case. A balun may be helpful on the booster input. It might be located at some distance from the input if needed to avoid oscillation of the booster. Booster input and output are shielded coax cable connections to keep output of the booster from getting back into the input where it could cause trouble.

The ARRL Antenna Book, 19th edition, on page 11-2 says: "Yagi free-space gain ranges from about 5 dbi for a small 2-element design to about 20 dbi for a 31-element long boom UHF design.

A diamond shaped rhombic antenna comes within 3-db of the 31-element yagi and is non-critical as to spacing. It is not so likely to be recognized as a high-gain TV antenna.

A Channel-29 rhombic can be two #8 copper wires (more or less) which measure about 13 feet long, separated in their middles by about 6.5 feet, giving an overall length of 11 feet for the antenna.

Connect the wires at one end to a 680-ohm resistor, give or take 150 ohms or so. Point this end of the rhombic at Miami.

Connect 300-ohm twinlead to the other end of the rhombic. One twinlead wire to each rhombic wire. Run the twinlead to the TV-type 4/1-impedance balun used with the booster input.

Connect output from the booster to the TV with a shielded coax cable.

Erect the antenna as high as possible and watch for CH-29 and other UHF channels.

Best regards, Richard Harrison, KB5WZI

I don't have test equipment like SWR meter,
impedance checking meter whatever.

Currently I am overwhelmed with information
regarding antennas. Folks have offered what sound
like good suggestions, however, with terms and
technology I don't understand at this juncture. I
basically just want something that will enable me
to enjoy using my HT while pedaling my trike -
right now-. Then later develop a better antenna.
I live is a very hilly area. It seems that if I
construct something or modify (like a mobile whip
and add a ground plane) it would be a beneficial
to check it out with appropriate test equipment.

<Hmmm I wonder what folks did before the MFJ -
259B or whatever.>

It seems like at this point and without any test
equipment (except a $15.00 Radio Shack LCD
multi-meter), the best solution is just to take
the antenna that I have on the HT move it up in
location (approximately 5 feet above the surface
of the road and 2 feet above my head). I could
then keep the HT on my belt and safely use it.
That is unless, it would negatively impact the
radio. Then in the interim I could study the ARRL
Antenna book, figure out how sophisticated I want
to be with antennas. Then purchase the equipment
that will fit the parameters I name.

Jim,
Even removing and mounting the HT's antenna on
the trike will mean you'll have to check to see
how well it's working (swr, or how well the radio
likes the antenna), just moving the antenna will
change things enough that you'll have to re-tune
it. Your best bet is to find someone locally, or
maybe one of the radio shops, that can loan you
a meter, or check the antenna for you. Even so,
you'd still be better off using a 'mobile' antenna
rather than the one off of the HT.

3956. MULTEE Antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-26 04:55:35 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3C7B1579.8987670C@bellatlantic.net>
Source record: 147793

In the 22nd edition of Bill Orr's Radio Handbook on page 27.24
Figure 38 is something called a MULTEE antenna. Made
completely from 300 ohm open wire TV line as a T with the top
looking like a folded dipole 70' long fed by the vertical part 52'
for 160/80 meters.

No matching device is shown. Instead, 50 ohm line is shown directly
connecting to the vertical feedline on one side, with ground radials
and the other conductor in the twinlead connected to the shield side.
But the text says "The antenna evolves from a vertical multiwire
radiator, fed on one leg only."

How the hell is this thing supposed to work? Where did they come up
with 6000 ohms and the linear loading "match", which doesn't work
out mathematically or at the antenna I built. See the quote from the
book below. I don't see how a quarter wave 300 ohm line matches
6000 ohms to 50 ohms. I came up with 547 ohms needed for the
matching section, assuming a 6000 ohm antenna load. (I measured
the damn thing. The VF was .76 with the TV wire I used and it
was a 1/4 wave long for 80 meters. It doesn't work worth beans on
receive, with or without a transmatch. I didn't bother trying to
transmit. Test equipment was an MFJ 259 and an ICOM 745.
An LDG MP AT-11 autotuner does tune it to a match on both
80 & 160. Maybe it works poorly because I used regular
foam dielectric TV line - but that doesn't answer the matching
question.)

Here's the text:
"On the low-frequency band, the top portion does little radiating so it
may be folded horizontally to form a radiator for the high-frequency
band. On the lower band, the antenna acts as a top-loaded vertical
antenna, while on the higher band, the flattop does the radiating,
rather
than the vertical portion. The vertical portion, instead, acts as a
quarter-wave linear transformer, matching the 6000-ohm nominal
antenna impedance of the 50 ohm impedance of the coaxial
transmission line". (I think "of the 50 ..." is a typo in the book
and should be "to the 50 ...")

Most HT antennas do not work well when they
are not connected directly to the radio because the
radio itself is part of the ground plane. Those of us
who enjoy "bicycle mobile" have better luck with
antennas that do not require a ground plane. Comet
now makes a mobile antenna that has a spring on it
yet is an end-fed (half-wave) antenna on two meters.

Of course, it is a different story on HF. The only HF
that I ever did from the bike was on ten meters, and
let's just say that it is a good thing that the HTX-100
is pretty tolerant of bad matches.

For more info on being "bicycle mobile," see:
http://www.lafetra.com/BMHA

> Then later develop a better antenna.

Of course, but there is little worry with the newer
"no ground plane" antennas.

> <Hmmm I wonder what folks did before the MFJ - 259B or whatever.>

We used our SWR meters and took lots of data points,
but I am glad to have my MFJ-259, especially for HF.
Note that the position of your body on the bike will
greatly affect your antenna's performance in many ways.

That will work very poorly as described above.

> I could
> then keep the HT on my belt and safely use it.

It is not safe to be tethered to the bike by coax!
1/8" connectors are one thing, but your belt could
stay *very* connected to your bike in the event of
a mishap. If you insist on doing this, at least have
in-line some phono-type coax connectors. Yikes!

Source record: 147796

I suggest that you begin with a simple and inexpensive SWR meter. This will tell you if the antenna you construct or buy presents a reasonable impedance to the HT. If it doesn't, the HT won't deliver full power to it. Beyond that, you're best off testing your experimental antennas under actual conditions, on the road. It'll be hard to beat something like a ground plane or J pole. Either of these might be improved by adding a couple of baluns, one at the feedpoint and another about a quarter wavelength below, but then again they might not -- it depends on the feedline length, ultimate path to ground, and how the feedline is oriented relative to the antenna. So experimentation is best. Listen to repeaters or simplex stations as you travel. In a lot of cases, you'll hear a chopping noise, often called "picket fencing", which is due to the same signal reaching you by various routes, some longer than the other, and all interfering with each other. You'll find that this will be worse on some antennas than others. Try talking to various repeaters, and see how the antennas compare. All else being equal, height will help, so put the antenna up as high as you practically can. RG-58 is perfectly adequate for a feedline.

For a commercial antenna, I like a half wave, like the AEA Hot Rod, for this kind of job. I know MFJ makes a similar antenna, and some other manufacturers do also. You could homebrew one, but the matching network is probably not for a beginner. The nice thing about a half wave antenna is that a ground plane isn't needed.

This is the only place where there is a problem. The booster is best
placed at the antenna, not near the receiver. But I don't know if there
are boosters with the proper impedance available.

You don't mention the distances you want to work. For regional work on 40/80, a regular old coax fed dipole will outdo either of the antennas you have now. Probably the most difference on 80m. For DX, a vertical can be good, but you have to consider a good radial system if you really want it to work well. I'd probably go the HF2V of those two. It's fairly proven on 80/40. It's a full 1/4 wave on 40m at 32 ft tall, and it can work 160 and 30 with add on kits. But if you just want better reports within 1000 miles, I'd switch to dipoles instead of the slopers, etc. You could also shunt feed the tower as a vertical. That would be a fairly low cost route that should outdo the HF2V on 80m. MK

I'm not sure, but it sounds like you are neglecting radials. You need
1/4 wave radials to act as the lower half of the ground plane. They
also act to decouple the feedline from the antenna. Without radials,
the coax can radiate and skew the pattern upwards off the horizon.
This effect will show on transmit and receiving. Adding radials, and
better decoupling could greatly improve the performance of the antenna
if you are not using them now. I'm not sure how you made that one, but
I often make small VHF ground planes from SO-239 connectors.
You can use stiff thick wire, or thin rod as the elements. With the 4
mounting holes, you have an easy way to connect four radials. I
usually slope them downwards at 45 degrees. It sounds like you may
well need a yagi for good reception. 3 elements mounted vertical would
likely do the trick. Very easy to make for the air band. As far as
gain and efficiency, I consider them two different animals. Gain is
the manipulation of an antenna pattern to increase effective power on
one direction over another. Any time you have gain in one direction
you must have a decrease of gain in another. Efficiency is the amount
of power that is radiated by an antenna vs losses. Loading,
matching,ground, or otherwise. You also have feedline and connection
losses. All these combine to calculate the ERP or effective radiated
power. You can have an antenna with 10 db gain, but if you lose 85% of
your power in the matching device, no bueno. Not to worry about the
simple ground plane for VHF. At any decent height above ground , one

with 4 radials will be very efficient. It has little gain, but what gain it does have is at a low angle if it's a few feet up. If a well decoupled ground plane doesn't cut it, make a 3 or 4 el yagi. Sounds like it may be kind of a weak tower. Not all are equal. MK

Hi Kevin--

Bullseye! I know we've got more literature on the Lindenblad at work, so I'll take a look. Two meters is pretty close to the airband--the design in the article might scale with minimum of effort...

Thanks!

Rick K1BQT

Joe already has the booster. I am guessing it is like most consumer
boosters. It may be in a box like a tuna tin with two or more "F"
connectors and a power cord emerging. The "F" connectors are supposed to
be 75-ohms, in and out.

Best regards, Richard Harrison, KB5WZI

EHS, Jr. wrote:
"How the hell is this thing supposed to work?"

I don`t have my copy of Orr`s handbook handy. But 6000-ohm loads are possible as are 50-ohm sources. To match these, a "Q-section", quarter-wave transformer, may be used. Impedance needed for the matching "Q-section" is the square root of the product of the end impedances.

50x6000 = 300 000, sq rt 300 000=547.7ohms, as EHS, Jr. calculated.

That may be close enough to 300 ohms for an appropriate impedance transformation in the case of this"T" antenna. I don`t have the required information , but decided that on this newsgroup, that`s customarily no inhibition.

Best regards, Richard Harrison, KB5WZI

Uplink is still via telephone, and where I live that means about 28k max.

Also, having used a satellite system, there is considerable lag time between requesting a page and actually showing it on the screen. For simple pages, the 28k phone system is sometimes much faster.

No the com VHF band is from 118.000 to 139.995 mhz AM generally 25khz steps but in 2006 it will be 8.33 khz steps also the Military freq is 225.000 to 399.995 Mhz. The middle of the band is 121.5 mhz (also the emergency frequency 121.5 , 243.000 mil). If the run from the antenna (a disk cone would be best for this purpose , and it's cheap) could be RG-58 or better RG-8 but if the run is a hundred or more feet TMR-400 (I think that's 9913 but don't quote me) would be better. If the Airodrome he is trying to lisen to is a larger airport the Altitude of the base transmitting station will usually be elevated , ie a tower , and have a 50Watt TX but if it's a small field it may be lower and have a power of only 3 to 10 Watts. You can see this is a bigger problem. Also Obstructions like mountains can make a big difference. The answer is not to simple .

I remember that my parents had a similar device attached to their RCA shortwave set. It was a black cylinder, _thoroughly_ potted with some hard, black substance with #16 stranded leads and a thumbscrew on the case labeled 'Ground'. The thing disappeared years ago, probably disassembled by one of my brood. I do remember the marked improvement in reception when it was attached to the radio, so it apparently worked.

> TMR-400 (I think that's 9913 but don't quote me)<

Dielectric is different. 9913 uses air-spaced poly (that spiral stuff) and LMR-400 is foam poly. LMR is supposedly less lossy at higher frequencies (and, from my experience, acts less like water hose).

>The middle of the band is 121.5 mhz<

Check your math--Jim is right.

BTW, looked at the roof of MHT and the FAA center in Nashua, NH today and didn't see any VHF Lindys or spiral-wound biconals. Just good old verticals. Got to ask a friend who's an FAA tech if they're usning them around here.

3988. WANTED: your suggestions on 2m/70cm directional antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-27 02:21:45 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0202261821.11b473bd@posting.google.com>
Source record: 147826

I am debating which 2m/70cm directional antenna to buy.

The URLs for the products are:
http://www.arrowantennas.com/146-437.html
http://www.cushcraft.com/amateur/details.asp?catid=183
http://www.mfjenterprises.com/products.php?prodid=MFJ-1768

I'm not familiar with directional antennas or satellite communications, so I need your help. I'm looking for a compact directional antenna with plenty of gain, and while I haven't tried satellite communications, I would like to try at some point in my ham career. (I already have good omnidirectional antennas.)

What are the pros and cons of these three compact 2m/70cm antennas? I am leaning towards the Arrow II Satellite Antenna, as it has excellent reviews on eham.net, has a handle for portable operation, and promises satellite capability. (I assume the latter is made possible by the optional duplexer.) In other words, it seems to perform at least as well (I may be wrong) as the other two with much more versatility. Is there any reason one would prefer the MFJ or Cushcraft? Are there other options I should consider?

First let me tell you I am trying to do this as cheap as possible. I bought a little dig camera the other day, and I have really enjoyed taking pics with it,,, but , (there is always a but), I have to buy a battery for it about every 85 pictures. It is a 123 3 volt lithium battery ,pilelithium. And they cost about two for 11$. What I would like to do is 'rig' up a power source, maybe 12 or 6 volts and then 'divide' it down to the needs of the camera. A while back I 'had' something , kind of like a wall wart except it had varibale voltages , and you could 'swap' the positive and negtive poles. I have a couple of 'mixed' ideas, but hope you can clarify what I need. I hope you can 'see' what I am trying to say. hihi. thanks in advance. cl. 73

CL,
The hard part would be to find/make an adaptor to fit
in the battery compartment. From there, just run a line
to a 'bat-pack' of whatever kind of batteries you have,
wired so that you have 3 volts output. Ten 'D' cells in
parallel, connected in series with ten more 'D' cells in
parallel, should last awhile. And Eveready will love you!

Do it with, say, 4 pairs of NiMH AAs, and you should be able to get
good life and rechargeability.

Buy a bunch of the 2AA holders at Rat Shack, wire them in parallel,
load them up with Rayovac or Energizer NiMHs, and make yourself a
carrier from a cheap fanny pack. The $20 Rayovac charger will charge
four pairs overnight.

No sir, the com VHF is from 118.0 to 136.975. Not generally 25 kHz. steps, but REALLY 25 kHz. steps.

> but in 2006 it will be 8.33 khz steps

Only if Europe has enough clout to pull it off. How those idiots got us off the digital divide-by program is beyond me. I do not for one second believe that we will be going to this bastard system.

>The middle of the band is 121.5 mhz (also the emergency
> frequency 121.5

No, sir, the middle of the band is (sqrt ((118^2 + 137^2)/2), or about 127.5 MHz.

>> The answer is not to simple .

The answer is trivially simple. Toss up a vertical dipole and see if you can hear ANYTHING. If you can hear a signal embedded in the noise, a good gain antenna may do something for you. If you hear noise only, nothing I know will help.

True, but the impedance of the antenna (if I read right) is about 300
ohms, not 75 ohms.

But then I would probably connect an impedance matcher to the antenna
input, the booster to the matcher and the coax to the booster.

The closer the well shielded booster is to the antenna, the better.

When discussing RF safety, many of the calculations refer to a "near field." The only explanation I have found for what this is seems rather vague from the ARRL Antenna Book 17th edition (c) 1996, which describes the "near field on page 1-19 as "an area roughly bounded by several wavelengths of the antenna."

Is there anything more specific...like how many wavelengths?

You can look at the near field as the volume (not area) within which the intensity falls as 1/r (where r is distance from radiator) and the far field as the volume--extending out to infinity-- for which the intensity falls as 1/r^2. All in free space, of course.

When we talk about 'communication', there are few examples where the antenna is in the near field. When we talk about 'exposure', it is usually when we are within the near field.Of course, there are always practical exceptions to both, but these are useful rules of thumb.

The transition region is roughly 1/8 wave from the radiation source, for a point source. But gain antennas have non- trivial apertures, or at least 'effective' apertures, so they extend the transition zone often beyond a wavelength or more; much more for a high gain antenna.

A low gain antenna, such as a 1/2 wave dipole, is certainly within the far field when the separation is several wavelengths, say, 3. Of course, the 'pickup' antenna has its own transition region and commonly this antenna is a high gain antenna itself.

Kraus's 'Antennas' has a nice discussion, but I'm afraid I have no ham pub pointers.

Jim Weir wrote:
"Why would you cut it for the middle of the NAV band when he is trying to receive COM signals? The center of the COM band is 127.5 MHz."

Why would you try to make a receive antenna exactly 1/4-wave?

A ground plane or similar vertical antenna which is "too long" gains signal from vertical angle directivity as it grows from 1/4-wave to 5/8-wavelength. That`s a frequency ratio of 2.5 to 1.

A vertical antenna cut for 1/4-wavelength at 100 MHz will increase in gain along the horizontal all the way up to 250 MHz.

In 1949, I worked at a radio station on 1320 KHz. That station operated on a tower built for a 740 KHz station. The 1320 KHz station didn`t suffer from the extra height. In fact, the height was a big benefit to the station. It concentrated the radiation along the horizontal plane which increased the station`s service area.

Today that station is still operating on 1320 KHz on the same tower.

The same directional gain, lowering the vertical radiation angle, would be true for a vertical antenna 1/100th the length and operating at 132 MHz.

A non-resonant antenna is reactive but matching networks fix that and adjust the resistance too.

In a receiving antenna, mismatch reduces signal, but it also reduces noise. At VHF and UHF, there is less noise to reduce. It does help to maximize signal to overpower internal noise at these frequencies in the receiver.

Best regards, Richard Harrison, KB5WZI

Richard,

Thanks. Apparently, the text just omits the idea that the
transformation afforded by the 1/4 wave section is only
intended to get things "close enough". I received some
E mail, suggesting as much, just as your post does. That
seems reasonable to me - and the impedance at the
feedpoint is within the range of the autotuner.

I still am trying to understand where the figure 6000 ohms
nominal for this antenna comes from. I neither challenge
it nor agree with it - I just don't know. But learning more
is fun! (Frustrating, too.)

Dunno, never have done that. However, if you'd express the interest to Dr. Shuch, I betcha he'd do it if he could. The League may have copyright on it and they get a little touchy about that from time to time.

W4ZCB
Actually, a whole lot touchy and lots more often than I think they should.

4014. Re: Stainless steel tubing for elements & boom for UHF antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-27 17:48:06 UTC
From: Jim Weir <jim@rst-engr.com>
Message-ID: <u7q6u3dbtrnleb@corp.supernews.com>
Source record: 147852

That's an interesting question, and one that I hadn't pondered before. Stainless has a bulk resistivity somewhere around 50 to 75 times that of copper (alloy-variable), while aluminum is about 1.6 times that of copper. Now given that skin effect will keep this wave in the top few mils of the surface, might we not expect to see a measurable and perhaps significant loss when using stainless over aluminum?

I don't know; I haven't run the tests.

Because all things considered, it is the best compromise between efficiency
and antenna pattern over the full bandwidth.

>
> A ground plane or similar vertical antenna which is "too long" gains
> signal from vertical angle directivity as it grows from 1/4-wave to
> 5/8-wavelength. That`s a frequency ratio of 2.5 to 1.

You are correct that the E-field pattern changes towards the horizon as the
antenna gets longer relative to a quarter-wave. You are incorrect in that
to match and get the advantage of this horizontal gain you tighten up the
bandwidth significantly. The original poster was wanting to hear the ENTIRE
com band, which is a 15% bandwidth. This is a nontrivial match at BEST, and
when you put in a matching network, the bandwidth shrinks concomitantly.

>
> A vertical antenna cut for 1/4-wavelength at 100 MHz will increase in
> gain along the horizontal all the way up to 250 MHz.

And unless you use a matching network (sort of beyond the capability of the
original poster, don't you think) that "gain" goes to loss in one hell of a
hurry.

>
> In 1949, I worked at a radio station on 1320 KHz.

Yes, and your transmitter had a pi-network on the output that would match a
knitting needle to a barbwire fence over a fraction of a percent of
bandwidth. What did the station care what the bandwidth was? They weren't
going anywhere.

>
> A non-resonant antenna is reactive but matching networks fix that and
> adjust the resistance too.

And reduce the bandwidth simultaneously. There ain't no free lunch.

>
> In a receiving antenna, mismatch reduces signal, but it also reduces
> noise.

So does a resistive pad. I don't recommend it, however.

At VHF and UHF, there is less noise to reduce.

You wanna try that again? Last time I looked, there WAS an "f" factor in the equation.

Jim

> for much of what they make. I just grin and bear it.

Having added to the ranting about MFJ quality (or the lack thereof),
I should include my opinions on the other side as well. I complained
about the switches on my '259B analyzer, but boy, I do use that thing
often, and it sure makes my life easier. Bad switches and all.

When I'm working HF, I can tune the antenna without QRMing the world.
The 259 puts out only about 20 mW while I adjust the antenna tuner to
the band. I may change bands several times in a few hours, so this
saves all of you from a lot of QRM. [hrrmm - I wonder if even that
little signal bothers someone somewhere?]

When I'm up on the rooftop adjusting a new VHF antenna, it sure is a
lot easier to get it tuned when I can quickly scan for the frequency
with the lowest SWR. The tweak-and-check cycle time is a LOT faster
than with a traditional SWR meter.

Bob, KI8AB

P.S. - When my beam is pointed the right way, the 20 mW from an MFJ is
in fact enough to key up a repeater about 5 miles away!

Bill nelson wrote:
"But then I would probably connect an impedance matcher to the antenna input, the booster to the antenna input, the booster to the matcher and the coax to the booster."

That is a superior arrangement in an ideal situation. Loss in the coax between antenna and booster hurts the signal to noise ratio. Twinlead isn`t so bad. It has only about a third of the coax loss.

Joe can`t readily get another booster made for antenna mounting, or for mounting indoors for that matter. He probably has to work with the booster made for indoors, that he already has. Providing a-c power to an ordinary booster mounted at the antenna might also be a problem.

The little "matchbox" coil balun that he might use is probably available from some TV repairman. This will also probably be an indoors device.

My concern was that if something could go wrong it might be the balun`s susceptibility to signal leaking from the output of the booster. A little distance provides a lot of isolation. The radiated signal loses 22 db in its first wavelength of radiation and 6 db every time the distance doubles after that. So, just a few feet of coax at 560 MHz is a lot of distance away between the balun and the booster to get some isolation and avoid oscillation. The wavelength is about 54 cm (21 inches).

The total transmission line system, with its twinlead, balun, and short length of coax will only have a few db loss if all the components are good. Care in affixing the "F" connectors is probably the most taxing part of the exercise.

Best regards, Richard Harrison, KB5WZI

4022. Tesla coil transmitter/ antenna?

Source record: 147860

I believe most Tesla coils resonate around 500 Khz or less, but I have heard of some operating in the low hf range, around 2 Mhz. Has anyone tried using Tesla coils to send CW or AM? Most Tesla coils use an LC network for tuning, but it may be too broad to be useful as a transmitter. Perhaps a long wire can be attached to the LC network to act as an antenna.

Interested in any thoughts, opinions, or actual experience in this area.

Cross-posted to: comp.jobs,sci.research.postdoc,sci.electronics.design,rec.radio.amateur.antenna,misc.jobs.offered

Not sure what budget range you are looking at.

For basics of digital modulation, try Agilent Test & Measurement application and tech notes searching for keywords "digital communications" or product "89441" and "E3238":
http://www.tm.agilent.com/classes/MasterServlet?view=library&language=eng&locale=US

Agilent (HP), Lake Stevens Division (Measurement Systems), gave a seminar in 1998-99 timeframe called "Surveillance Forum" which showed capabilities of their vector signal analyzers in digital comms analysis. Contact an HP rep and see if you can get a copy of the notes.

An adequate text on digital comms measurements is:
"Telecommunications Measurements, Analysis, and Instrumentation", Dr. Kamilio Feher, ISBN 1-884932-03-7.

For hardware, look for electronic warfare and vector signal analyzers equipment:
http://www.condorsys.com/
http://ewhdbks.mugu.navy.mil/contents.htm

For your consideration.

mm

4029. Monoband mobile coils vs multiband?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-02-27 22:36:52 UTC
From: Gary - KJ6Q <davison7@gte.net>
Message-ID: <8cdf8.5415$G7.3650@nwrddc01.gnilink.net>
Source record: 147867

It's my understanding that monoband antennas using coils for matching purposes are more efficient -
all things being equal - than larger multi-band coils using taps for various bands - but have not
seen actual data as to what percentage losses might be involved...

I have arrived at a 20/40 mobile designe that seems to provide excellent efficiency on both bands,
and I'm wondering how much loss I might be experiencing due to the dualband tapped coil as opposed
to 2 separate antennas/coils...

Comments?

I've got a question about the readings from my MFJ-259B. On 40m,
I use a 75m dipole fed with 3/4WL of ladder-line. The MFJ gives
the following readings.

6.79MHz SWR=3:1, R=16 ohms, X=0 ohms
6.94MHz SWR=2.4:1, R=25 ohms, X=3 ohms
7.00MHz SWR=2.2:1, R=40 ohms, X=15 ohms
7.04MHz SWR=2.3:1, R=49 ohms, X=19 ohms

Seems to me the resistive part of the impedance is changing much
faster than it should which causes the minimum 50 ohm SWR to be
somewhere other than the resonance point of 16 ohms. Has anybody
else seen the feedpoint resistance change eight times faster than
the reactance? Is this a characteristic of full-wave dipoles?

Conducting a site survey to determine the feasibility of receiving signals from a specific terrestrial source is always a good idea, and I don't mean to dis Jim's suggestion for doing that. However, in my view, simply sticking a dipole into the air and making a snap go/no-go assessment is like doing the foreplay and then leaving town when it's time for sex. I say this because, for OTH VHF signals, a sample taken in one spot may yield nothing while another taken 10-20 feet away might yield a readable level. Haven't we all rolled the car ahead at a red light to pull the FM radio out of a null--or seen a TV antenna stuck on a 5-foot pole in the middle of the lawn because that's the only place where the signal comes in? At most spots on my roof, I couldn't hear the tower using a hand-held groundplane on a 6 foot pole. Yet, with an 11-dBi gain antenna 25 feet above the same roof, I hear the tower (and a lot of other stuff) just fine. Bottom line, if you're going to go to the trouble to make a survey antenna, put it on a real long stick and move it around to as many locations as you possibly can. You may get lucky and find a great spot where you won't even need a gain antenna.

As a postscript, the aviation standard for clear reception appears to have a built-in margin of safety that would probably accommodate a Narco Omnigator with soft tubes and a blown ballast cap on the vibrator. If you want to monitor a tower from a fixed spot, you can literally do about 50 dB better than that with a good antenna and a hot receiver.

Along these lines, please be aware that the 259 IS a low power
transmitter (not you specifically, but everyone in general). It is very
easy to leave it on and cause QRM to some local VHF users. I've keyed
my repeater with mine hooked to a gain-type omni directional antenna at
40'. My repeater is 30 miles away.

Best to turn it off when you aren't making measurements.

Gary

As a science project in 8th grade I made a spark transmitter (a Model T spark coil with an LC network), and a "Coherer" receiver (A matching LC network, a glass tube with iron filings detector, and a buzzer to shake the filings loose when they stick). I managed to transmit a total of 20 feet between 5' long parallel antennas! Sort of similar to the Tesla Idea. I don't think the FCC would approve.

Thanks Mark. I did manage to do some further research into my question earlier today. I agree that the FCC probably wouldn't approve because the transmitted frequency would be way too broadbanded and many harmonics would be generated, especially with a length of wire as an antenna extension. Bad idea I guess.

Chip, N1IR wrote:
"You can look at the near field as the volume (not area) within which the intensity falls as 1/r (where r is the distance from the radiator) and the far field as the volume--extending out to infinity--for which the intensity falls as 1/r^2. All in free space, of course."

That predicts a faster decline of the summation of the fields beyond the point where the near field has significance, just as it should.

In the far field, power can be determined and expressed in watts per square meter perpendicular to the propagation of the wave, or in volts per meter in the wave or a wire best positioned for induction of voltage in the wire.

The far field decays due to spreading of the radiation. The volts per meter decay linearly with Chip`s "r' (distance from the radiator) in the far field. The watts per square meter decline as the square of the distance from the radiator. At twice the distance there is 1/4 the power, hence the "inverse square law".

Arnold B. Bailey in "TV and Other Receiving Anntennas" discusses "Near Field and Far Field" in detail in chapters 5 and 6. Bailey says the near field is the complex summation of three fields. The electric vector (voltage) decays as the cube of the distance. The induction field decays as the square of the distance. The radiation field decays inversely (linearly) as the distance grows. So, the radiation field predominates in short order.

That reactive electric field declining as the cube of the distance fades first and fastest. It soon counts for nothing. The reactive induction field is next to go and it fades as the square of the distance. Then the radiated field is left traveling alone for practical purposes in the far field. It fades linearly with distance. We are dealing with volts per meter, not watts per square meter, and the like values of the reactive components of the field were considered.

From a point source, Bailey says the radiation field predominates over the other two fields beyond about 10 wavelengths. Bailey says a lot more about the topic, but you need to read the book.

John E. Cunningham in "The Complete Broadcast Handbook" extends the definition of "Near and Far Zones" to a dividing line as:
D^2/2lambda
Where D is the largest dimension of the antenna, and lambda is the wavelength.
D and lambda are expressed in the same units.

At this dividing line, the induction field and radiation fields are equal, but at greater distances, the induction field fades rapidly.

Best regards, Richard Harrison, KB5WZI

This is not correct- Home Depot and Lowes both sell vinyl paints that attack the surface of vinyl derivatives and adhere extremely well- so well it can even be used on vinyl seat covers.

I have not found my prized copy of the Orr Handbook, so this is a guess. High impedance such as this, likely comes from something like an end-fed 1/2-wave, some multiple thereof, or something close, any of these having an open-circuit at the far end.

As Reg recently pointed out, the half-wavelength does not repeat the open-circuit through the distance of a half-wavelength because there is radiation taking place in a radiation resistance. The antenna is accepting power, proof of a feedpoint resistance considerably lower than infinity.

I found my Orr Handbook and it appears to me that this antenna is bogus.
The horizontal folded dipole section is 35 ft for 75m/40m. I modeled it
using EZNEC and the impedance is NOT 6000 ohms. It is around 3+j600 ohms.
The SWR on the 26 ft vertical section is very close to infinity on 75m.
This looks like a really terrible 75m antenna.

Well, you know, with all these extra radios laying around, you could start a real decent business. What you do, is you send a radio to each of the people on the following list, then take the name from the top of the list, move all the others up one space, and add your name at the bottom. You then send this list to all the hams you know, and they do the same. In a month, you'll have five thousand radios, and can get your own store going.

1. KD5NRH
2. KD5NRH
3. KD5NRH
4. KD5NRH
5. KD5NRH

(Don't laugh; I actually got one of those chain letters from some guy who had used five variations of his own name, each with a different PO Box address in about a 20mi radius of his actual address)

>under two bucks, pretty reasonable.

That's pretty close to retail around here; just a hair over $20 for
the charger, and 1600mAh AA or AAAs are $10/4-pack. C & Ds are a bit
pricier, but still well worth it for the radios that use them.

IIRC, the charger comes with coupons good for about $5-10 off
subsequent battery purchases.

I'm a real big fan of not dumping several pounds of extra trash into
the landfills, so I only use alkalines where they actually do some
good. (i.e. flashlights and emergency kits, where self-discharge is a
potentially serious problem)

Gary,
I'm not sure I can agree with your 'understanding' about monoband antennas, or that there would be any appreciable difference in efficiency between antennas using descrete coils per band, or a tapped coil for multi-bands.
Given that the only difference between those two 'type' of antennas is the loading coil, I would think that any difference in efficiency would be in the coil structure and not in if/how the coil is tapped. (I'm assuming your refering to the 'extra' coil turns not being used, or that are shorted, and the shorting lead.) If the only difference in the two antennas is the loading coil, and if we're talking about using a 'shorting lead' or just clipping the 'extra' coil turns off, I don't see where there would be any ~practical~ difference in efficiency on HF. There would be a difference in convenience in not having to stop and change taps, though.

Hi Richard,

On this forum its often difficult to judge the level of the answer some folks request, hence my pithy version.

Of course, if I had asked the question, I would have preferred your answer:-)

Frankly it always amazes me that some people who actually do antenna measurements don't know or care about the difference between the two, and also how often many people assume that a compact range must (in all cases) be far field.

..or that one can do a single, very near field measurement of an extended aperture and claim it tells you about the far field ;-)

73,
Chip N1IR

>> the intensity falls as 1/r
>> the intensity falls as 1/r^2
>> (where r is the distance from the radiator)

Does this mean that when r=0, the intensity is 'infinite' ?

Is the boundary between the near and far fields a perfect sphere centred on the antenna ?

Does the field 'switch gears' from 1/r to 1/r^2 instantly ?

Does it matter that more accurate theories don't even include the concept of 'field' ?

All above are rhetorical.

J. Harvey, Ottawa

Hi Gary, We need more information on your mobile installation:
1. What is the antenna size and material? Length, diameter?
2. What are the dimensions and material of the loading coil?
3. Where is the tapped coil placed on the antenna? (bottom or middle?)
4. What kind of additional matching circuitry + feedline is being used?
5. Where is the antenna mounted on the vehicle?
6. What type of vehicle is it?
7. What type of soil is it being driven over?
8. What color is the vehicle? (Only kidding...)

All of the above (minus #8) will effect relative efficiency.

Offhand I'd say it's not too difficult to get decent efficiency (>50%) on 20 meters with an 8' base loaded whip and it's very difficult to get usable efficiency (>30%) on 40 meters due to the low radiation resistance. So there's not much you can do to mess things up on 20, and not much you can do to make things good on 40.

I painted my BB3 screwdriver PVC cover with Krylon brand spray paint.
It has held up very well in the sun, and shows no sign of peeling or
other form of deterioration. I used white. Have to watch for any
metal ingredients if you use a color.

J. Harvey wrote:
"Does it matter that more accurate theories don`t even include the concept of "field"?

It may be instructive to review what a field is supposed to be.

A force field surrounds an electric field. This is demonstrated by bits of paper attracted to a hair comb when conditions are right.

Another force field surrounds a moving charge as is demonstrated in an electromagnet, or the compass needle and the wire between battery terminals.

The intensites of these forces is measured by the force exerted on an electric charge within a field as is demonstrated by electrostatic or magnetic deflection in a CRT (cathode ray tube)

B. Whitfield Griffith, Jr. in "Radio-Electronic Transmission Fundamentals" lists 9 of the ways positive and negative charges can be separated:
friction, chemical action, thermoelectric action, electromagnetic induction, electric induction, thermionic action, piezoelectric effect, photoelectric action, and radio activity.

Once charges are separated into concentrations of positive and negative charges, an electric force field exists in the space between the positive and negative charges.

Griffith says charges don`t move a motor rotor, the force of the magnetic field causes rotation. He also says, voltage doesn`t produce plate current in a vacuum tube, it`s the electric field between plate and cathode.

Griffith says the preceding is prologue to the fact:
"When the transmission line terminates in an antenna, we must understand that the fields are simply changed in shape, that they keep on going into space, complete with power, but without benefit of voltage or current."

Best regards, Richard Harrison, KB5WZI

J. Harvey wrote:
"Does this mean when r = 0, the intensity is "infinite"?"

Infinite voltage produces an infinite electric field, and infinite current produces an infinite magnetic field. These aren`t found in a radiator.

The fields already exist in a transmission line, feeding an antenna, and are merely reshaped, by the antenna, as they are launched into space. The intensities of the fields surrounding a conductor are consistent with the voltage and current of the conductor.

In texts, depictions of fields are seldom perfect circles around all conductors in all cases. I have no quarrel with most representations.

There is no gear shift at the demarcation point between near field and far field. The fade of individual constituents of the electric and magnetic fields around a conductor is continuous but they don`t all fade at the same rate. It is a fact that the farther the fields are from an antenna, the less energy in the fields returns to the antenna. The demarcation point is an arbitrary human choice. One definition is: the point at which energy in the induction field equals energy in the radiation field. You are free to make your owen definition.

Best regards, Richard Harrison, KB5WZI

I'm not sure if you mean the loading coils, or the matching coils, but
if you mean the loading coils, the difference won't be huge on 40/20.
I've got two 40m antennas. One a multiband coil and a tap for 40m, and
the other is single band 40m. I can tell very little difference
between them in everyday use. But I haven't done a direct comparison.
It's best to use a single band coil, I know that, but I've never
actually done an A/B test to see how much difference there is. If you
mean the matching coil, Dunno about that as I use a small tuner for
impedance matching. It works all bands. Never tried a single coil
matcher such as a "dollar special". It may be a slight improvment over
my tuner. I should try that sometime. MK

No problems. I built a 6m 3 el yagi totally from copper tubing. I used a torch and brazed the elements straight to the copper boom. Even the gamma match is copper tubing. Works great, but is a little heavier and easier to bend than an aluminium antenna. But I've had no problems so far. I used hard copper. Mine is starting to turn green/brown a bit, but has no effect. I am using a UHF/VHF antenna on the roof for digital TV and I am having some trouble getting the signal strength needed. I find the signal fluctuates and I have to rotate the antenna to from time to time to pick up the same channel. It does look like multipath. I can move the antenna to a different spot on the roof, but before I do that a couple of questions. First the antenna is on one side of the roof and is pointed toward the other side. The roof has asphalt shingles. I wonder if the multipath comes from the roof. In the line of sight of the antenna about 100' from its location are a row of pine trees. Could they be a factor? Any help or suggestions would be welcome.

I assume by "digital TV" that you mean broadcast HDTV, correct?

Was the antenna designed specifically for broadcast HDTV?

Was it installed recently?

What kind of lead-in (300ohm twinlead, rg-59 or rg-6 coax)?

Broadcast HDTV is UHF. Many older TV antenna slighted their UHF
sections. Only solution is a better antenna system.

<snip>

Extract of Richard Feynman's speech as he accepted his Nobel Prize in Physics, 11 December 1965.

"Well, it seemed to me quite evident that the idea that a particle acts on itself, that the electrical force acts on the same particle that generates it, is not a necessary one-it is a sort of a silly one, as a matter of fact. And, so I suggested to myself, that electrons cannot act on themselves, they can only act on other electrons. That means there is no field at all. You see, if all charges contribute to making a single common field, and if that common field acts back on all the charges, then each charge must act back on itself. Well, that was where the mistake was, there was no field."

So the field strength around an antenna only follows the '1/r' or '1/r^2'
laws when it happens to feel like it ? When it gets too close to the
radiator, then these "laws of radio physics" break down ?

These are rhetorical questions.

:-)

You can try Mouser or Digikey.

> as a Shortwave Antenna ?

Depends how short the shortwaves are !

Ask a silly question - get a silly answer... :-)

Or two:
Since many people have used a short piece of wire (or even a bedspring) as a shortwave antenna, then 'YES' you could connect your portable shortwave radio to it, but then you would have to perch yourself beside it (probably uncomfortable). Might as well use a random wire just by itself.

More seriously, many shortwave broadcast stations also make their broadcasts available on various satellite subcarriers. If you have an old C-band satellite system, you might try disconnecting it from your TV and try some browsing for audio signals. If you're interested in shortwave, then you would probably enjoy browsing the satellites.

Why not try latching relays?
they only need power to switch then back and forth , other than thay they stay in the position you switched them too .(IE)you power the latch coil and the contacts shift, release the power they stay shifted

power the reset coil and they shift back to the original position and stay there

I have the following scanners for sale...

1.) Regency Z-10 professionally converted from 10 to 30 channels with beep-delete and audio enhancement mod.Radio is a SOLID 9 out of 10 both cosmetically and functionally, and includes back-of-set antenna and power cord (no box or booklet).Scanner is in AMAZING shape for its age and is housed in an attractive, wood-look cabinet with LARGE bright green LCD display . Covers 30-50/144-174/406-512 Mhz. $40 SHIPPED

2.) Bearcat BC-12 CRYSTAL 10-channel base unit. These are quite rare to find, and this one is in BEAUTIFUL, virtual MINT condition (SOLID 9 of 10 !).Has scan speed adjustment control and delay on/off switch. Includes antenna and power cord (no box or book).Works and looks great..a must for collectors or, as a reliable backup radio ! $40 SHIPPED

Radios shipped by USPS parcel post. Insurance optional if requested as is different shipping method for additional cost as per USPS rates. If interested or have any questions, feel free to Email me @ any time. All replies answered. Payment via M.O. or personal check (w/ 14-day waiting period for clearance).

Thank You and Happy Monitoring !!

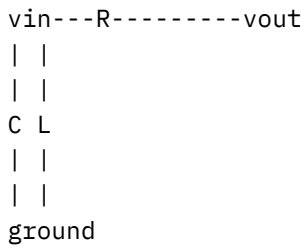
4087. HELP needed in understanding Bode Plots

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-01 03:22:33 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0202281922.2bf73b9d@posting.google.com>
Source record: 147673
Cross-posted to: rec.radio.amateur.antenna,alt.engineering.electrical,sci.electronics.design,sci.electronics.basics

NOTE: This is NOT a homework assignment. (I graduated from college nearly 6 years ago, so there is no grade at stake.) Yes, I am truly interested in understanding how filters work.

Can anyone help me with the Bode Plot for the following bandpass filter circuit? Have I stumbled across limitations of Bode Plots?



As usual, the input voltage is on the left and the output voltage is on the right.

The transfer function is H(s)=vout/vin=sL/(s^2*CLR+sL+R).

If R=100 ohms, C=100 microF, and L=100 mH, then the transfer function is:
H(s)=.1s/(.001s^2 + .1s + 100) = 100/(s^2+100s+100,000)

The dB of the transfer function is:
HdB(w)= 10 log [(.01 w^2)/(.01 w^2 + 10^4 (10^-5 w^2 -1)^2)]

The phase of the transfer function is:
Hangle(w) = -arctan[100 (10^-5 w^2 -1)/(.1 w)]

The poles of the transfer function are s=-50+-j312.2498999

This means that the cutoff frequency is 321.2498999 radians (around 49.7 Hz). But why isn't this cutoff frequency 316.227766 radians? I realize there isn't a very big difference between these two frequencies, but the second one is the resonant one.

And why is the dB slope per decade irregular? The cutoff frequency is 49.7 Hz, and the gain is near 0 dB here. At 497 Hz, the gain is -29.8 Hz. At 4970 Hz, the gain is -49.9 dB. The gain is -30.0 dB at 4.97 Hz and -50.1 dB at .497 Hz.

Can someone tell me how you would draw the Bode Plot for this circuit?

The answers to the question below are that I am talking about HDTV. The antenna was not specifically designed for HDTV, in fact to be honest it is a rather inexpensive Radio Shack VHF/UHF antenna, medium gain. It has been installed for one year and I am using coax to connect to the TV. I believe that it is RG 59. It is definitely not RG 6. The antenna is about eight feet above the top of my chimney and I hate to raise it further, or at least at last resort.

Actually, the cutoff frequency is not exactly at the resonance,
because cutoff is defined as the 3 db down points on each side of the
response peak.

But he way I think of the frequency shift of the peak is like this:
If the resonance of the LC were lossless, each cycle would last a bit
longer than if energy is draining out of the resonance while it is
ringing down from some starting energy. This raises the exponentially
damped frequency just a bit compared to the undamped resonance.

Given the transfer function 100/(s^2+100s+100,000), 316.23 is the undamped natural frequency of the circuit. If the resistance was very low, the circuit would have resonance at that frequency. However, the resistance lowers the resonant frequency of the circuit to the 'damped' natural frequency. If you plot your transfer function in fine detail, you will see it peaks a little below the 312.25 value you might expect.

As far as creating a bode plot, in this day of computers and such, you should use software such as Matlab, or even Excel for that matter to do the plotting. If you must do it by hand, the simple rules for asmyptotes apply far from the resonance. Near the resonant peak you must apply a correction factor based upon the Q of the circuit. I don't know, do they still teach this stuff in school? Not much point with the software available today.

Cheers,

dave y.

Aren't most Digital TV signals not actually broadcast in HDTV, but only in SDTV (Standard Definition) ? For example, the famous Super Bowl was broadcast in SDTV, not HDTV (to many complaints). The reason that I'm asking is that many people seem to think that digital TV is always HDTV when I read that most isn't. Just curious if I missed a memo...

Given that the Digital TV signal fits into the same channel bandwidth as the old analog TV signal, what does it mean for the TV antenna to be "Digital Ready" or "designed specifically for broadcast HDTV" ? It may be that Digital TV happens to need more gain than analog TV, but "higher gain" is a more well defined meaning than "digital ready" given that people might live close or far.

[snip]

You might want to download the very simple (yet quite effective) program
called "PC-Ecap" from:
http://ourworld.compuserve.com/homepages/circuitsys/PCECAP.HTM

This is a circuit analysis program, rather like a poor man's SPICE. Yes, it
runs in a DOS shell, and you have to manually create a text-based input, but
for simple networks like you are asking about, it is amazingly effective. It
creates a Bode plot as an output, for defined input conditions.

It won't help you with the theory, but at least you can see the results of
different trials, which may help you gain an understanding of the network.

For the above circuit, you only need to type 4 or 5 short lines of text,
then start the simulation.

Bob.

Ken,
This is one of those times when bigger is better, to
a point. Personally, I'd try for about 1 1/2 wave on the
lowest band I was going to use. The second harmonic of an
antenna doesn't usually 'work' too well. The 'extra'
half wave on the lowest band in use should get you away
from the second harmonic on all bands. But, if you've got
the room for larger, why not??
'Doc

Wouldn't that have a very high input impedance on that lowest band? Of course if you use the right length of open wire feedline, as Cecil W5DXP would surely recommend, that won't matter.

> The second harmonic of an antenna doesn't usually 'work' too well.

I'm not sure what you mean by this. If you mean that antennas don't work well on twice the frequency for which they were originally designed, I suspect most people who use loops that are a full wavelength in circumference on the lowest frequency band would strongly disagree with you.

If you don't find anything in your country, you might want to check out
www.antenex.com. They're a commercial antenna manufacturer near
Chicago, Il. USA and sell several well made antennas just for that
application. They might even have a European outlet.
Another possibility is www.tessco.com, a general commercial radio
wholesaler who does business worldwide, you might be able to
work with them as well.
Good hunting!

Back in the black and white TV days, one of the best all channel VHF antennas was built by Channel Master. They all quickly disappeared with the advent of color TV. Reason? Phase roll across the passband, which didn't affect B&W, but shifted the color phase differently on different channels - unacceptable to the audience. HDTV occupies the 6 MHz channel fully with a rectangular chunk of signal. Phase and amplitude need to be very nearly the same across that 6 MHz, a requirement met by few off-the-shelf antennas.

DTV can carry SDTV or HDTV. The biggest need for American
HDTV reception is a directional antenna. I have found that matching
the antenna properly with proper signal levels can make a difference
between intermittent reception and perfection. Gain is much
less important than a reasonable directional antenna.

I get excellent indoor reception with a bow-tie and a low noise (but
low gain) preamp that feeds two HDTV recievers. My indoor UHF
antenna provides for reception of my UHF HDTV channels, but one
of my DTV signals is on VHF, and I have combined in the output
of a fixed position rabbit ear antenna also.

If you are in a difficult reception area, the impairments can accumulate to
provide you an unreceiveable signal. If you have a reasonably directional
antenna, and are marginally getting the signal, you might want to be prepared
to deal with the antenna/feed-line/TV-front-end matching issues. In my
own circumstances, by adding a preamp (I mean a high signal level capable
one), the reception seems to improve markedly. Gain isn't always the problem,
and in fact, too much gain can be a worse problem than too little. TV
front-ends aren't always a very good match for the feedline, and antennas
are also not always a good match. If you can put a preamp close between
the antenna and feedline, you can mitigate rather heinous response curves
because of matching issues.

Frankly, it is sometimes easy to overload a preamp in strong signal areas,
but in such areas, the signal can be strong enough to overcome other
impairments. In medium strength signal areas, solving the problems
can be a bit of an artistic endeavor, because of the various mismatches
involved.

I had mitigated my indoor reception problems by using a low gain/low noise
preamp next to the indoor antenna (it isn't immediately next to the TV), then
I pad the output of the preamp, but it provides a nice 75ohm match to the
coax. I haven't done anything with the match on the TV side, but if I
had continued ot have intermittent reception, I would have done something
about the match on the TV side also. The extra few dB of signal quality (since
my desired channels are all across the TV spectrum) affords consistant
reception on all channels. I have been 'hit' by severe rainy/windy weather
than has caused some intermittent reception, but the environment for my
antenna is horrid. Above the roof, my reception would be totally trivial.

> Hz and -50.1 dB at .497 Hz.
> Can someone tell me how you would draw the Bode Plot for this circuit?

The asymptotic slopes are each about 20db/decade - no problem here. It
appears that you are looking for the asymptotic Bode plot made up, in this
case of a line rising at 20db/decade up to the corner frequency (due to the
zero) then falling at 20db/decade(adding in the effect of the poles. Try
superimposing this on your plot. Remember, the straight line asymptotic plot
is an approximation.
If I am wrong I hope that I will be corrected- it is considerably more than
6 years since I did a Bode plot

Jim Weir wrote:
"Because all things considered, it is the best compromise between efficiency and antenna pattern over the full bandwidth." (To cut the 1/4-wave vertical antenna for the center of a band with a width of 15% of the center frequency.)

TV antennas need wideband response. Arnold B. Bailey in "TV and Other Receiving Antennas" has a catalog of antenna characteristics. It includes the antenna`s bandwidth as a percentage of center frequency.

Bailey gives the bandwidth of a 1/4-wave vertical antenna with a radiation resistance of 28 ohms and a 52-ohm coax feed as 18% for 1db down and 40% for 3db down in response.

When frequency rises above the quarter-wave frequency, radiation is concentrated toward the horizon, producing gain. Also, radiation resistance rises. A 10% increase over the resonant frequency will give about 50-ohms resistance plus an inductive reactance

When frequency falls below the quarter-wave frequency, the radiation resistance falls below 28 ohms and a capacitive reactance is added. So, not only does operating the antenna below resonance reduce its gain, operating the antenna below resonance also worsens its mismatch to a 50-ohm coax.

As this antenna has a 40% bandwidth, and as the antenna gets worse below resonance, and as the antenna gets better above resonance, it makes sense to resonate it at the low end of a 15% of center-frequency bandwidth, instead of the center of the band.

Best regards, Richard Harrison, KB5WZI

From looking at the other posts, I think that there is some confusion here. A bode plot is not simply a plot of gain against frequency. It is the _straight_ line approximation to the frequency response obtained by examining the poles and zeros of the gain function. This can _only_ be done if the poles and zeros are sufficiently apart from each other.

As a technical statement, the bode plot fails for resonance's, i.e. there are no n*20.db/decade straight line approximations to the real curve. i.e. you can _not_ draw a "bode" plot for such resonance transfer functions. It should be noted that a normal frequency response graph is not a bode plot, although the term bode plot is often used indiscriminately to apply to such general smooth curve frequency response plots.

"At VHF and UHF, there is less noise to reduce."

Jim Weir responded:
""You wanna try that again?"

Yes. At VHF and UHF, there is little sky wave or ground wave propagation. So, except for noise generated nearby or far out in space, there is less noise as compared with lower frequencies. Of course, receivers have internal noise to compete with weak signals.

Richard....

Having spent the better part of half a century in my specialty of designing and testing aircraft VHF antennas, you aren't going to convince me to use an antenna longer than necessary, nor am I going to sway you out of your convictions. So be it. We both have our reasons for doing what we do, and that is fine. I'm happy with mine and you are happy with yours. Let it be. I'll be glad to start throwing my experts against your experts, but all we will achieve is to confuse the group.

To the person who started this thread, I have a question. Have you tried an outside antenna and did it do any good?

Jim

>frequencies, but the second one is the resonant one.

You presumably define 'resonance' as the frequency at which the
reactances are equal and opposite or at which the circulating current is
a maximum. But the 'cut-off' frequency, by which I suppose you mean the
frequency at which the output voltage is a maximum, is NOT at the same
frequency.
>
>And why is the dB slope per decade irregular? The cutoff frequency is
>49.7 Hz, and the gain is near 0 dB here. At 497 Hz, the gain is -29.8
>Hz. At 4970 Hz, the gain is -49.9 dB. The gain is -30.0 dB at 4.97
>Hz and -50.1 dB at .497 Hz.

The response curve is only *approximately* symmetrical with a
logarithmic frequency scale.

Note that your LC circuit contains *no resistance*. This leads to many
anomalous results of calculation for the LC circuit alone: for example,
the Q is infinite and the bandwidth is zero. It is just the presence of
the source resistance R that makes the overall characteristics finite.

I run mine on a little 12VDC supply which plugs into an AC power supply socket. There is an RF choke in a long DC supply lead wound on a ferrite rod. Can still be used in the hand-held mode.

It lasts for ever.

Well Yes and Know , but I would put up the big loop first feed it with open wire line and it should do a good Job for you.. will act some what like a rhombic on the higher frequencies.. and you may want a vertical or dipole up as well because the higher you go in Frequency the deeper the nulls become.. but also the greater the gain in the lobes of the antenna pattern. Anyway had a 600 footer up for several years here was a great antenna unfortunately the ice strom of 1998 took down two of my supporting trees so it will be long time for them to grow back.

Also you may wish to take a look a L.B.'s fine work on Horizontal loops at

This antenna appears in my old ARRL Antenna Book and the RSGB Handbook
I have
(4th edition, I think). The dimensions vary slightly in various
publications,
some shing open-line and others Twin Lead. The RSGB book credits the
antenna's origin to W6BCX. Looks like the design has been around for
40 years
or so, but I've never heard of anybody actually using one.

All of the descriptions show a set of ground radials at the base, too.
Did your model include radial system, Cecil?

The descriptions say that on on 80/75 meters the antenna is basically
a
loaded vertical, which looks reasonable. Works out to about ~1/10 wave
vertical section with a BIG capacity hat. Operation on 40 is a bit
more fuzzy, but it looks to me like the idea is that the folded dipole
section doesn't do much loading on 40 because the vertical section is
pretty close to a quarter wave. Or perhaps the FD section causes 3/4
wave resonance on 40.

In any event the antenna is highly dependent on a good ground/radial
system.
The thing can't be looked at as a bunch of transmission lines because
the
parts all radiate somewhat.

Who was/is W6BCX? Maybe he knows.

(snip)

As I learned it, a Bode plot is the actual phase and amplitude plot versus frequency with the amplitude and frequency scales plotted as logarithms but the phase plot to a linear scale. There are no inherent assumptions of any approximations on the plot, though, if the poles are real and well separated, one can approximate the actual Bode plot with straight lines and rounded corners and get pretty close to the actual Bode plot. Now that I have Mathcad, I can make accurate Bode plots of any circuit I can describe by a LaPlace transform with no approximations or pole zero placement restrictions. I don't think making an accurate plot makes it any less of a Bode plot.

Well John, I would have to say that you learnt this incorrectly. There is no doubt, that a "Bode Plot" refers to the straight line asymptotic approximation to the real frequency plots. This was certainly the way I first learnt to some 24 years ago, probably 2nd year of my degree.

The fundamental point of a "Bode Plot" is that you find out all the poles and zeros of a response and draw straight lines between them. That _is_ indeed why it was invented.

>Now that I have Mathcad, I can make accurate
> Bode plots of any circuit I can describe by a LaPlace transform with
> no approximations or pole zero placement restrictions.

That is not a Bode Plot. It is a normal frequency response plot.

> I don't think
> making an accurate plot makes it any less of a Bode plot.

It does. A frequency response curve is just that, a frequency response curve. It is not what is defined as a "Bode Plot". I agree that this is a very common misconception, but I am sure if you have a look on the web, you could find the original paper by Bode where he introduced this method.

Think about it this way. What would you call this specific method of using straight line approximations?

I agree, except that '24' should be '45' (;-). The areas between the
real response and the straight line approximations are called 'Bode
fillets'.

LOL Harvey !

Well see, i dont have a professional equipment, just got a new SONY
ICF-SW7600GR and i love it. It seems to pull out signals from afar,
especially Marine and Amateur Radio, using SSB. But i am using the supplied
Reel Antenna to hang outside the window to do it.
After browising through many Antenna models and manufacturers.. i dont know
as to which will suit my Radio, since i am scared that such high power
antennas might damage my radio. The one from SONY especially AN-1 and AN-LP1
are expensive. Anyone has any idea about these antennas ?

So i thought if i can use that thing in anyway. Looks like i need to perch
under the dish and use it eh harvey ? lol

So harvey, how do i connect that coaxial cable that comes into the house
from my dish into the radio ?
Because my radio has a mini plug called.."Ext Ant" looks like a RCA jack.
And how do i prevent Lighting and other factors from affecting my set.

Hi Dennis,
I am just getting the hang of this whole radio thing, though i remember in my younger days, my dad used to build them using Valve Tubes (yes they were all SYLVANIA and made in USA). I think the magic lamp is something yet to be replicated in todays electronics.

I plan to get my HAM license and probably buy a JRC -NRD 545... Oh well.. dont have that much money now though.

So i would appreciate of any information on how to convert that C-Band Satellite Dish to be of use in radio communications.

Hi Jason, there's no reason yet why it should be much worse than other antennas of the same size. Some of the criticism on this newsgroup is unfairly biassed. People are jealous of the publicity it has accumulated.

But it's a pity the inventor didn't give it a better name. What about "Screwcatcher" or " Bugsdriver" ?

Far be it from me to promote myself as an antenna guru, and I defer to Doc, at al, on this.
However, I believe there would be *some* difference in discrete coils and a tapped, multi-
band single coil. It's because, inspite of being "tapped", those jumpered turns "try" to load as well. Since these turns aren't truly "shorted", but rather "bypassed", they still factor into the
equation. That is not to say that such an arrangement doesn't work--it does---, but suffice it
to say that, IMHO, there is *some* effect from it. I have heard of coils catching fire due to this, but never experienced it myself. I used a Texas Bugcatcher for a number of years this way.

I do, however, believe that this is one of the reasons screwdriver antennas work so well---be-
cause any unused coil turns are down inside the mast and, in effect, are part of the mast itself.

David or Jo Anne,
I wouldn't even guess at what the impedance would be
on any band, and it really doesn't make a lot of difference
when using ladder-line and a tuner. Personally, I prefer
using a tuner rather than Cecil's method. I have the tuner
and don't have the switches or relays.

Usually the second harmonic of an antenna doesn't work
out too well. An 80 meter doesn't 'work' very well on 40,
a 40 on 20, etc. I can't help it if someone doesn't like
it, or disagrees, it's just what I've found to be true in
most cases. (I'm one of those people who use a full wave
length loop on the lowest band I can 'do'.) I think that
has more to do with radiation patterns than anything else.

IMO, that's an old wives' tale. Consider that an EDZ is known
to be a very good antenna with gain over a dipole. An EDZ is
1.28 wavelengths long. Wouldn't it stand to reason that a 1.0
wavelength antenna would have characteristics between a 1/2wl
dipole and a 1.28wl EDZ?

I believe this old wives' tale has it origin in coax fed antennas.
For sure, feeding a 6000 ohm dipole with coax resulting in an
SWR of 120:1 will burn up almost all the signal in the coax.
But feeding a 6000 ohm dipole with 450 ohm line (or 600 ohm
line) results in an SWR of 13:1 (or 10:1) which is perfectly
acceptable with ladder-line. If the antenna system is fed at
a current maximum point on the ladder-line, the impedance seen
by the transmitter is about 34 ohms with a 50 ohm SWR of 1.5:1
which is a perfectly acceptable SWR even without an antenna
tuner. With open wire line, that impedance is about 60 ohms,
again perfectly acceptable without a tuner.

My 130 ft dipole used on 40m almost always outperforms my 40m
1/4wl vertical with 8 elevated radials. On 40m, I feed the 1.0
wavelength dipole with 3/4 wavelength of ladder-line. That odd
multiple of 1/4wl transforms the high impedance at the antenna
to a low impedance acceptable to the transmitter.

>

Hi Reg:

Your first statement is correct - it should not be much worse than other antennas of the same size. However, the criticism it has received has not been based on that premise. The criticism that it has received is based entirely on the ridiculous claims made by its proponents:

1) That placing an inductor in series with the antenna causes the feed current (not feed voltage) to be time delayed thus allowing the H-field to be in time phase with the E-field.

2) That bringing the E-field and H-field into time phase causes the antenna's radiation resistance to increase from less than 1 ohm to 50 ohms.

3) That the antenna [the radiating element] has 100% efficiency.

4) That it has a bandwidth far greater than any other antenna, regardless of size.

5) That the antenna will respond only to radiation and not to individual E- or H-fields (the source of man made noise), thus it is very quiet.

etc.

Criticizing these claims has little to do with jealousy.

Source record: 147718

Hello all,
I just purchased a Heathkit SA 2040. I opened it up, to check its condition, which overall is excellent. I have a question about the connections of the internal balun, for anyone who has actually worked on, or seen the inside of their own tuner.

The Balun, T1, in my tuner, has 4 white wires. Two of the wires are marked with a white cloth tape, and two are not. Of the two that are not marked with tape, one goes to J4 and one to J5 (the balanced wire hookups, on the back of the unit). Now to the problem. Of the two wires that are marked with tape, one is connected to ground, and one is tinned, but is not connected to anything, and it doesn't look like it ever was.

I don't have a manual yet, (so it may tell in the assemble procedures) but I did down load a copy of the schematic from the I-net. The schematic just shows three wires, One to J4, One to J5, and one to ground.

I would like help from anyone who has one of these units, and has hooked up the internal balun in the past.

Thank you,

Scott

Agree. Bode Plot refers to the straight line asymptotic
approximation to the real frequency plots. It's a short-cut
to get an idea how the circuit responses.

Cut off frequency is the -3dB point on the 2 sides of the response
curve. Resonance frequency is the point of max output. They are
not the same. The separation is affected by the Q-factor.

This show that you are indeed correct, about your age. I have not heard of the
term 'Bode fillets' before.

Hi Kevin,

The complete reference is (Jason, take note):

"Network Analysis and Feedback Amplifier Design," Hendrik W. Bode,
Ph.D., Research Mathematician, Bell Telephone Laboratories, Inc., D.
Van Nostrand Company.

Bode exhibits BOTH representations. The point of the lecture series
this text grew from was the characteristics found in feedback
amplifier design. Bode's choice of illustration and the suite of
views were tailored to this. As such, "Bode plots" are a statement of
style and application.

I recently made a loop antenna with about 98 ft. of #14 insulated wire. I am feeding it with about 50-60ft. of 300 ohm twin leed wire into the tuner on my rig. My question is, would the impedence too high using 300 ohm twin lead? Also, I have the wire lying on the perimeter of the roof of my house. A friend says when it rains, the SWR will go crazy. Any input on this is appreciated. The loop is recieving great and I'm getting out ok. I just hasn't rained yet to see.

I call that an approximate Bode plot, based on asymptotes. Bore plots, from my education are the frequency response that produces an easy to approximate form and one that allows easy visual identification of many real and complex poles and zeros, by virtue of the log log format. I was schooled in both exact and approximate versions. In all cases, the format (log log amplitude and log linear phase) was what was referred to as the Bode plot form of frequency response presentation. I guess you have not, so far convinced me that I was taught incorrectly, just because you say so.

I am having trouble actually understanding your overall meaning here. Anyway, the main utility of the bode plot is this.

Draw the straight line asymptotes relating to all of the poles and zeros for the open loop gain and closed loop gain. These slopes will all be n*20db/dec. If the intersection of these two plots intersect at a rate of <20db, the system will be stable. There are pathological cases where this is not strictly true, but by and large, is correct enough for the majority of applications. The utility of this approach is that it includes conditional stable systems, i.e. systems that have gain greater then unity and net phase shift of zero, yet still be completely stable. For example, if you do an n multy pole rolloff, then introduced n-1 zeros just before the intersection point, although the phase goes way over -180 (in an inverting system), the system will indeed be stable.

We will probably have to agree to disagree. I made another post on how the
asymptotic slope point of view is used in practise.

EZNEC sez that's about the feedpoint impedance of a
one wavelength dipole.

> Another figment of your old-wives' imagination ?

Hope not. Does EZNEC have an imagination?

> Unless you have something to contribute, don't bother.

What is your estimate of the feedpoint impedance of a
one wavelength dipole?

Might be OK... OTOH, one of the problems with multipath can often
be cured by a better front/back ratio on the antenna, which usually
(in consumer TV antennas) comes along with higher gain.

> installed for one year and I am using coax to connect to the TV. I believe

One year means it probably has not weathered too badly.

> that it is RG 59. It is definitely not RG 6. The antenna is about eight

"not RG-6" is not good... RG-6 should definitely be used. It has
less loss and better shielding than rg59 (the other typically used
"tv" coax). Radio Shack rg-6 wouldn't be my first choice either...
Home Depot usually sells a decent brand for less than the RS price.

I hope you used decent matching transformer at the antenna, and made
sure all exterior connections to the coax are well waterproofed.

The preamp as someone else mentioned might help, if weak signal were
the problem. (preamp at the antenna) But it sounds like that is
not likely the issue.

> feet above the top of my chimney and I hate to raise it further, or at least
> at last resort.

8ft is pretty good, if you can get decent LoS at that height.
Raising higher than that is a pain (more guys, etc).

Directionality and LoS is still a question...

It's a plus to that design, but I'm not sure how big an impact it has
on the performance over other factors such as coil placement, length
of mast below and above the coil etc. I bet a "tapped" bugcatcher on
40m using an 80m coil is just about as good as any screwdriver in
overall performance. The bugcatcher might lose a small tad from the
tapped coil, but it might make up for it with the usually longer lower
mast that the bugcatcher has. It's the lower mast length of most
screwdrivers that scares me away from them. It doesn't seem too easy
to add lower masts to them in order to raise the coil height. The coil
height on a given antenna length is probably more important than
whether the coil is tapped or not. Of course, if he's looking for the
utmost in performance as he was earlier, then I'd use a bugcatcher
with a fixed coil. Most screwdrivers I see have way too short a lower
mast for optimum performance. Of course, I may be seeing mainly lousy
screwdrivers though. I know one I checked out was a sorry device. You
were the one that told me about the guy that built them, and his "easy
SWR with high coil loss" theories. It was horrible overall. The coil
was junk, too low also. I'm sure yours are way better... MK

Mark,

It isn't hard to make an SD with a long lower mast. I saw one at a hamfest on a van that had
a 6 FOOT lower mast. This allowed the guy to bumper mount and still get the coil above the
top of the van. I've been meaning to build one as an experiment. After all, if it didn't work,
I can always cut off the bottom, right? I see no reason for the long lower mast not to work.
The one I saw was configured like the bugcatcher you describe; long lower mast, short whip
with a cap. hat.

I'd almost bet the the 3" Texas Bugcatcher and my Carolina Cyclone II (also 3") would be
just about equal. Hmm, maybe I'll "stretch" a CC II and see what happens.

Ya want one? <<g>>

There are several aftermarket manufacturers, one is Centurion:

http://130.94.151.161/antenna_2way.asp

They used to show a much more extensive set of choices, but this page should be a starting point. If you are unsuccessful, e-mail me and I will dig into my catalog file for the other manufacturers, whose names escape me for the moment.

98' would be like 3 wavelengths on 10 meters. It would work much better if you could make it 132', which would be one wavelength on 40, two wavelengths on 20, and 4 Wavelengths on 10. If it was that length, tuning would be much smoother since the antenna impedance would be from about 30 to 100 ohms. Would be much better if you could put the loop up on standoffs, so it isn't sitting in a puddle when it rains.

Bigger the Better! I had a 528' (4 WL on 80) loop of #10 THHN, and I could work Austrailia pileups on 40 CW at 4 in the morning with 200 Watts.. Fed it with a 4:1 Balun, 50 ohm Coax and occasionally a Johnson Matchbox. Performance on the other bands (10 was a bit finicky) was similar. Not bad for a multiband wire antenna!

Nope! To have any gain at all the dish has to be at least a "Few"
wavelengths across. Assuming it's a 10' (~3 Meters), you might get a few dB
gain on 220, but the antenna feed would be hairy, and very inefficient. Now
on High UHF (1296 MHz?), you might have something.

As I understand it, a quad element behaves as two half-wave elements 'stacked' with quarter-wave spacing. I don't see how you could do that with multiple-turns.
As for small loop antennas, they are well down in the negative gain range.

Hi Kevin,

Yes, I've no doubt of the trouble.

Issues of poles and zeros do not find much representation in what are
characteristically called "Bode Plots;" rather, they are inhabitants
of his first 300 pages of discussion relating to the complex frequency
plane. Bode does not go into the matter of "graphical computation"
until he establishes on pg. 315:
"A unit slope is evidently the same as a change of 6 dB per octave
or 20 dB per decade...."

However, Bode goes to some effort to describe on pg. 181 of his work
(Jason, take note):
"Theorem: The slope of the reactance characteristic of a general
reactive network at any frequency is always greater than that
of a simple inductance or capacity having the same reactance
at a given frequency."

On page 327, Bode provides a nearly identical treatment to Jason's
problem to illustrate the difference between theoretical and observed
differences in the network analysis.

He then on ppg. 337-338 (Graphical Computation of Relations)
illustrates:
"... it is sufficient to consider only one elementary
characteristic, the semi-infinite [unit] slope. ... For practical
purposes it is consequently preferable to regard the individual
finite line segments themselves as the elementary characteristics
upon which the analysis is based."
by showing three such unit slopes (correlating to three reactive
relations) combined (through addition of their slopes) into one
overall network characteristic. The material that immediately follows
goes into the nature of how these straight line approximations depart
from observed data on the basis of the inflection of the lines added

(the occurrence of sharp bends). Bode then goes to illustrate a simple RC circuit employing the second order approximation in section 15.5 "Illustrative Application of the Charts." Bode thus provides not only the first order approximation (noting is shortfall), but also the second order approximation, and the theoretical solution. None of the three are identical, but the second order approximation is very, very close; and Bode would argue, the first order approximation is sufficient.

No, two half-wave elements. Assuming a typical horizontal
configuration, the bottom 1/2 wave has its ends bent upwards and the top
half-wave has its ends bent downwards.
And thats why a 20 won't work on 10 because of the high impedance at the
feedpoint of a full-wave 'dipole'.

This, I think is wrong. It's quicker and more productive to play with Bode plots and casually inspect them in a thoughtful frame of mind than it is to mindlessly run a spiffy analysis program. In my experience these programs tend to stiffle the creative thought process. I find it especially useful to quickly sketch a few families of Bode plots and to make small scribbled notes on the same piece of paper, then contemplate the result, thinking of alternate circuit configurations. Most programs don't lend themselves to this process. My computer is usually turned on and dominating the desk in front of me as I do this but its serious role comes later on, in confirming, refining and documenting the design.

Note, one can be anywhere, sitting on the john or whatever, when playing with Bode plots, that's a totally cool aspect. Having memorized the phase shift of a few frequency ratios away from a pole location, one can use these to quickly sketch useful phase curves for the Bode plots.

Dipole implies equal poles, i.e. center-fed. If it is not center-fed,
then an adjective like, "off-center-fed", is necessary.

I am afraid I have to vote in favor of having a good live Bode
plotting tool, like Mathcad when doing basic design work. My latest
application involved design of a multi pole and zero active high pass
filter that had a gain of 100 in the pass band.
I developed the configuration by hunch and extrapolation of published
designs by using Mathcad to help me create a LaPlace transform of the
configuration under consideration and then give me a live Bode plot
(amplitude and phase) as I twiddled the component values, to explore
the performance and value sensitivities, trying quite a few
possibilities in a very short time. Then, with the lessons learned
(and hunches gained) with that configuration, select a new
configuration that (hopefully) minimized the weaknesses of the last
one, and repeat the process. In a day or two of work, I came up with
a configuration that had low sensitivities and made goo use of the
opamps capabilities. This method allows me to brainstorm a concept
and get real predictive results almost as fast as I can think, and
produces a publication quality printout of the work for me to put away
till I need to remember what I was doing. This is as close as
engineering gets to sculpting in clay.

Solving LaPlace transforms that take the real world properties of the opamp as well as an arbitrary array of passive parts is just not practical with a calculator and graph paper once you get above a couple poles and zeros. One of the solutions I produced was a LaPlace transform 23 pages wide. Mathcad produced a new Bode plot of 100 frequency points in less than a second each time I altered a component value in the network. As a final step, If I define a definition of the figure of merit for the filter, Mathcad will select the component values that maximize that figure of merit.

I think that I understand your idea. For transmit, the 'field' <smirk> is proportional to the current. More turns would seem to imply that you would have more contributions to the field. Unfortunately, the feed point impedance would go up with every turn and would reduce the current. It would be a losing proposition. Is this what you were driving at ?

4167. Re: MULTEE Antenna ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-02 03:00:31 UTC
From: richardharrison@webtv.net
Message-ID: <9742-3C804E5F-341@storefull-118.iap.bryant.webtv.net>
Source record: 147658

I found my "Radio Handbook" with the "MULTEE", a 2-band antenna for 160/80 or 80/40 meters. It seems the intent is to use the antenna as a folded dipole on the higher frequency and as a capacitively loaded vertical on the lower frequency. I think the authors or their staff made mistakes in the presentation.

The folded dipole has its first resonance at an overall length of only 1/4-wavelength, end-to-end. The conductor has a periphery or total length of about 1/2-wavelength which permits this resonance. 1/4-wave vs 1/2-wavelength for an antenna is a real space-saver.

The 1/4-wave folded dipole does not present 300-ohms to its feedpoint as the most common folded dipoles do. Maximum current in the 1/4-wave folded dipole occurs opposite the feedline, and 1/4-wavelength away from the feedline. That makes the impedance character of this antenna a lot like a short-circuit 1/4-wave stub. But, the antenna has a radiation resistance, so it doesn`t present an open-circuit to the feedline. The feedpoint of Arnold B. Bailey`s 1/4-wave folded dipole is 35.6 ohms.

At 80-meters, a twinlead Q-section is nearly 20 meters long, or about 65.6 feet. "The Radio Handbook" put the length of the folded dipole at 70 feet or a nominal 1/4-wave at 80-meters. The feedline length between the antenna and coax is 52 feet, which may have been intended to make some sort of match, but it steps the 35.6 ohm impedance up to a very high value, nowhere near 50 ohms. 46 feet of 43-ohm coax might have matched the antenna to 50-ohm coax. But, I guess they couldn`t readily find the 43-ohm coax.

A feedline could be made from two pieces of 75-ohm coax in parallel to closely match the antenna. Then any length of feedline could have been used with the antenna, within reason. The 35 ohm, or so, impedance presented to the the radio should be satisfactory.

At 160-meterss, the 1/8-wave folded dipole would present a very reactive and unsatisfactory load to a radio transmitter. I think a switch was omitted which would be used to reconnect the antenna as a loaded vertical antenna. The idea was probably to use a length of feedline that would resonate with the tophat at 160-meters. The radials shown in the handbook are evidence of this.

As Cecil said, as it stands it is a bogus antenna. But, with a little refinement, the idea will work.

Best regards, Richard Harrison, KB5WZI

I remember seeing somthing about this in CQ mag years ago. If I remember correctly, a two-turn quad (2-wavelengths of wire on a 1-wavelength form) has a feed impedence four times that of a single-turn quad--just as a folded dipole has a feed impedence four times that of a single-wire dipole. A two-turn quad--after you bring down the feed impedence to around 50 ohms with a 4:1 balun-- will likely show a greater >2:1 SWR bandwidth than a single-turn quad. Other than that, no particular advantage. Hope this helps. 73. Harry, VE3GRO

"Ravi R" was LOL:
Good ! :-)

> I am scared that such high power antennas
> might damage my radio.
I don't think that you'll every achieve sufficent gain on HF to damage a radio. But you might 'damage' the reception by overloading a front end designed for a 12" whip. If you hear signals on the 'obviously wrong' frequencies, then you might have too much signal.

> The one from SONY especially AN-1 and AN-LP1
> are expensive. Anyone has any idea about these antennas ?
I have the Sony AN-1 Active Antenna and it does pretty much exactly what it sets out to do. It is nice in that it doesn't need constant tuning (just a few switches to adjust once in a while). It more or less replaces a random wire.

> So harvey, how do i connect that coaxial cable that comes
> into the house from my dish into the radio ?
Are you asking about the use of the old C-band system to receive various 'interesting' audio ? You'll need a C-Band receiver to start. The SW radio might not enter into it (for starters anyway).

For the SW radio, just install a random wire to a convenient tree. Forget about the dish - unless you can use it to support the other end of your random wire antenna. :-)

> And how do i prevent Lighting and other factors from affecting my set.
Disconnect when not in use. Don't use when there is lightning about. Too much static anyway...

Hm. You seem to have stumbled across a new law of physics. The antenna must be radiating more power than is applied to it. If you can just figure out how to intercept a fraction of that power and use it to power the rig, you'll have invented perpetual QRM.

Yep, if there wasn't any loss, you'd just break even, with exactly the same field regardless of how many turns you use. But there is loss, and as it turns out, you end up with poorer efficiency with more turns. In a large loop the difference wouldn't be significant, but in a small loop it would.

True- except that the analysis programs are often used to replace thinking. In the old days thought was required. i.e. is the result reasonable? The programming capability does allow consideration of more realistic problems but the concepts behind those programs are important. Any fool can plug in numbers but understanding of concepts is needed to say whether or not the output is correct. The old adage GIGO (garbage in garbage out) holds. I particularily appliy this to income tax programs -my money is at stake!

In the days of slide rules, it was necessary to make an estimate as to the magnitude of a solution , just to set the decimal place. Since then, this has (regrettably been lost- if 2 times 4 as punched into a calculator gives 5.95 - that is assumed to be true. It was amusing to find that when one eyeballed an answer to a complex numerical problem, say 4, some student , 2 minutes later, after deep consultation with his calculator, would announce that the answer was 4.1.

> John Popelish

John,
You have the experience and background to look at the results that Mathcad gives you. How much of this is an intuitive, based on your knowledge, estimate of the reasonableness of the solution.. If the solution sets off a little alarm in your head, do you accept the solution or do you check your data input? I just did this today, on a simple problem -the results were different (particularly in phase) from what I expected from a "sit on the John analysis". It was a data entry error in a program which I wrote and tested some godoffal time in the past. A correction led to bliss.

I really think this is what Win Hill was referring to.

Mathcad is great (Oh to have had it as a student-maybe) for the reasons you say- the programming is great and well tested but YOU (excuse the shout) must be sure that the correct data is entered. Used with insufficient understanding can lead to disaster.

Jerry,
I don't 'see' how a 'shorting lead' and the unused
coil turns of a 'Bug Catcher' antenna are any different,
other than mechanical, than the unused coil turns inside
the tube of a screw driver antenna. The length of the
shorting lead does have some affect on things just as the
'finger-stock' (or whatever other method of shorting the
'SD' coils) does on the screw driver antenna. They're
both 'factored' into the tuning process on each antenna.
I don't think that there is any significant affect of
the unused coil turns of either antenna, especially at
HF. Even if there is, it's still 'handled' when you tune
the antenna. Right?

Apart from your reference to an ordinary gain verses frequency plot as a Bode plot (nails down blackboard sound....), I have to agree with you John.

Designs are just too complicated for pen and paper. I agree that you need to have the background understanding of what's going on, but design by pure simulation is very, very effective when used correctly. Its just a matter of moving on with the times.

As an additional point, even the plotting of AC gain can be dubious in designing a feedback amp. It is not uncommon to have designs that show good small signal ac stability, but in fact are unstable due to various non-linear effects. I generally just use the ac response as a general guide, but do all the stability work using transient analysis.

Like I said, just intercept some of that power and feed it back, and you're on your way to riches. Put 50 watts into the antenna having 200 watts ERP. Intercept 50 of those watts to run your transmitter, and you have 150 left over. Scale this whole idea up, and you can take your whole house off grid and say goodbye to your electric bills. You can even sell the surplus back to the power company, and before you know it you can quit your day job and retire in luxury.

I'll be watching for you on late night TV, sitting in front of the pool with the palm trees in the background, telling us all how you did it and how we can do it too for just 29.95 plus handling. . .

Yes, I know people in Italy that made the 40 mt, 20 mt and trying the 160mt
versions.
Some say that it performs well, other say so and so and other are in
trouble!
The only sure fact is that the specifications are not sure, but if you are
lucky you could have a medium performer short antenna, most for DX than for
local qso.

The difference is that the neutralized part of the screwdriver
coil below the finger stock doesn't carry much RF. Most of the
RF is flowing on the outside of the shorting tube due to skin
effect. OTOH, the shorted part of the bugcatcher coil is carrying
considerable RF.

In which direction? An extremely long wire turns into an end-fired
"array". If broadside radiation is desired, that wouldn't be a
good choice for an antenna. So "bigger is better" is subject to
a host of boundary conditions.

4192. how to install ground radials??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-02 14:11:56 UTC
From: AB Brown <abbrown@nospammail.com>
Message-ID: <a5qmn8$ug0$1@slb5.atl.mindspring.net>
Source record: 147530

I am planning on installing a slightly shortened ground vertical for 80 meters. I have never before worked with a radial wire grounding system, but I would like to install the 16 radials on the *surface* of the ground. I have two questions: 1) How can I install the radial wires so that I can continue to mow the lawn without the mower catching them? 2) Bill Orr's "Vertical Antennas" book describes chicken wire being used as an effective ground screen. I'd like an opinion as to the effectiveness of this wire as well as tips for installing it on the ground surface.

Thanks, in advance.

In addition to the beam spacing (phasing) being off, the takeoff angle
for the 20m quad on 10m is high, the opposite of what you want on 10m.
Turning a two-wavelength vertical loop on it's side (horizontal)
redirects the previous high angle radiation to a lower takeoff angle.

The same thing happens with a vertical. A two-wavelength vertical is
a lousy antenna for 10m because of the high takeoff angle but a two-
wavelength horizontal is a very good antenna for 10m - low takeoff
angles with four major lobes. (For the purists, I am using the term,
"takeoff angle", to signify the elevation angles of the maximum gain
vectors.)

AB,
Almost anything can be used for ground wires, it
just has to be conductive. Doesn't make much difference
if it's wire, or chicken wire, 6" pipe, or what ever.
One way of getting the wire under the grass is to 'stake'
it down, then let the grass grow over it. This would
be the time of year for it, too, I'd guess.

I'd use a roto-tiller (Set to till minimum width) to bury the radials a few inches, holding them down under the ground with home-made heavy gauge steel wire "Staples" until the backfill solidifies and the grass grows back. Nothing worse than hitting a ground radial with the mower!

Another means, IF you have good, soft topsoil, is to use a flat
(straight-bladed) spade to cut a "slit" in the sod, then push the
wires down into the slits with a suitably-sized piece of wood.
(This method won't work for me, as there is a CONSIDERABLE
amount of stone in the soil at my QTH.)

I'm thinking of mowing the grass REALLY close, then putting
in the radial system, using wire "staples" as someone else
suggested, then having a load or two of topsoil brought in
and spreading it over the area about 2" thick ... the grass
should come up through that ... if not, I can always re-seed
the area ... but this will have to wait until spring ...

The "chicken wire" approach could potentially present some
problems over time, if you use inexpensive material, as it
will corrode ... also, joints between sections should be bonded
well electrically, not just "overlapped" (IMHO). While more
expensive, I think you'll find if you research it that "professional"
installations use copper mesh ... not galvanized chicken wire.

Hardware stores have aluminum stake pins that work well for the purpose.
I assume they are for holding down the bottom of a fence.

That should work. I have experimented with non-resonant driven loops
and there seems to be nothing to prohibit such.

I use anywhere from #12-#16 stranded and double coated house wire. It resists breakage and corrosion. I have used this technique for years and have the same radials in the ground in a like new condition for 14 years. I lay mine "on" the ground surface and tack them down every 10 feet with U shaped wire fasteners made out of old metal coat hangers. In time the grass will grow over them and the lawn mower will not get them in the interim. Also studies have shown that radial effectiveness diminishes as the radials are buried. I have run experiments on 160 that have shown that radials in the form of a counterpoise 15 feet above ground produces the best far field field strength, followed by a counterpoise 5 feet above ground, then radials on the surface and then "in" the ground.

Construction Plans for the Model J146/440 Dual Band Solid Aluminum J-Pole

Parts Needed:

Radio Shack # 21-961   3/8”-24/SO239 Mount (Mobile CB Antenna) Radio Shack # 15-826   TV Mast U-Bolt Clamp Assembly
About 90 inches of 3/8” diameter Solid Aluminum Rod.
5 1/2 inch piece of strut angle Aluminum 1 1/2” X 1 1/2” X 3/16” Thick.
4 Stainless Jam Nuts 3/8-24 thread

Tools needed:

Drill Press with drill Bits up to 1/2”.
Tap & Die for 3/8-24 thread.
Sander or file to de-burr the cut edges.
2 9/16 wrenches & a 3/4 wrench. Vice-grips
 <A HREF="http://arrowantennas.com/inst/ijpole.html">J-Pole Instructions</A>
Make sure the piece of angle Aluminum is exactly 5 1/2 inches long. Drill 2 1/4” holes on one side, centered to fit the U-Bolt for mounting. On the other surface of the angle From the left side measure in 1/2” and drill a 1/4” pilot hole. From the left side measure in 1 15/16” and drill a 1/4” pilot hole. From the left side measure in 5” and drill a 1/4” pilot hole. This should give you 1 7/16” from center to center of the first 2 holes. This should give you 4 1/2” from center to center of the two outside holes. Redrill the left pilot hole to 1/2” Redrill the other 2 pilot holes to 11/32” Then tap the hole with a 3/8-24 Tap. Finish as required.

Cut a piece of the 3/8” Aluminum rod to about 21”. Attach a vice-grip to one end. Using a 3/8-24 Die cut in about 8 threads in the other end. Screw on the Coupling Nut that came with the SO239 Mount Tighten as much as you can. Measure the rod & coupling nut & cut to exactly 19 1/4”

Cut a piece of the 3/8” Aluminum rod to about 59” Cut another piece about 8” Attach a vice-grip to one end. Using a 3/8-24 Die cut in about 15 threads in the other end. repeat for the 8” rod. (If you don’t have jam nuts, cut

enough threads for 2 nuts & the thickness of the angle bracket.) Screw on one of the Jam nuts & tighten as much as you can. Measure from the bottom of the nut and cut the rod to exactly 57 1/2" Measure from the bottom of the nut and cut the other rod to exactly 6 1/4" (Remember the nut must be included in the Measurement.) (Put a small amount of grease on the threads) Screw the elements into the threaded hole of the angle bracket and tighten. Screw on the other nut and tighten it.
Attach the 19 1/4" element in the 1/2" hole using the rest of the SO239 Mount. Mount & test your new antenna.

SWR should be 1.1:1 at 146 MHz and about 1.2:1 at 144 &148 MHz.

SWR should be 1.1:1 at 443 MHz. and about 1.2:1 at 437 & 450 MHz.

Any math analysis requires confidence checking to assure that it has
been assembled and applied correctly. For instance, in the active
filter example I gave, I tested component values that should have
produced maximum gain (opamp open loop response), specific DC gain
(resistor values) and one capacitor at a time (sit on the john RC time
constant check) before I got into any serious design trials. I think
I found a couple errors in the derivation of the LaPlace transforms
this way, before I got it to work reasonably. But I don't see how not
having the tool is better than having the tool. You just have to
settle for examples that are simple enough to wade through without the
tool. I hated all the laborious math during my school days, but now I
actually look forward to seeing it all unfold and grind along at my
slightest whim. I ain't goin' back.

[snip]

Now that's what I thought. "Dipole!"

To me, "dipole" is plain English. Two "poles", or two equal sized elements with the feed point where they meet.

Cecil you are a connoisseur of semantics, a fan of the IEEE Dictionary, and you seem to have bought a copy of that "celebrated" volume, what does IEEE's lexicon have to say about this?

Personally, I believe that anything other than two equal elements fed where they meet, or if you wish, one element fed *exactly* in the center, is a dipole, anything else needs another name...

BTW... What does the dictionary say about "doublet"?

Reg:

Wire diameter and "end effects", relative to the wavelength in use, have an effect on the feedpoint impedance. Big loops at the insulator points, etc... affect the value. I have found that, in practice, somewhere between 2,000 Ohms and 10,000 Ohms is a useful range to assume. 6,000 Ohms is the arithmetic mean of those two "thumb sucks", and 4,500 Ohms is the geometric mean.

When you ran Dipole2, what "number" wire did you use, and how were the ends of the wires assumed to be dressed?

Source record: 147556
Cross-posted to: rec.radio.amateur.antenna,alt.engineering.electrical,sci.electronics.design,sci.electronics.basics

Thread:

FWIW... here's my thoughts...

In "design" I propose that there are really only *two* scenarios, each depending upon the initial condition of the sheet of paper on which the design is developed.

1.) Blank Sheet Design:

This is "conceptual design". You start with nothing and have no choice but to "create". In the patent world a design of this type would be referred to as a *concept patent*. Lot's of big picture creativity required, but little detail. Here, Hendrik W. Bode's wonderfully simple asymptotic graphing methods reign supreme! Computers are useless in this type of design!

2.) Non-blank Sheet Design:

This is "improvement design". In the patent world this type of design would be referred to as an improvement patent. The designer starts with some already given "concept design" and improves on it somehow. This can range all the way from simply "tweaking" element values to adding extra elements and perhaps deleting some already present. Not much *big* picture creativity required here, but lots of detail. Here the modern computer aided methods reign supreme. Bode does not provide much help here.

I have on my bookshelf above my desk a few "classics" to which I refer, often daily. The pertinent one here is:

Hendrik W. Bode, "Network Analysi and Feedback Amplifier Design", Third Printing, p. 551, D. Van Nostrand Company, 1945.

On the frontpiece it reads, "by Hendrik W. Bode, Ph.D., Research Mathematician, Bell Telephone Laboratories, Inc.

Somehow I doubt that the "title" Mathematician was appropriate for Bode, for IMHO... Bode was an *Engineer* of the highest calling.

Quoting from the preface, written by Bode himself,

"This book was originally written as an informal mimeographed text for one of the so-called "Out-of-Hour" courses at Bell Telephone Laboratories. The bulk of the material was prepared in 1938 and 1939 and was given in course form to my colleagues there in the winters of 1939-40 and 1940-41. During the war, however, the text has also been supplied as a reference work to a considerable number of other laboratories engaged in war research. The demand for the text on this basis was unexpectedly heavy and quickly

exhausted the original supply of mimeographed copies. It has consequently
been decided to make the text more widely available through regular channels
of publication."

H. W. Bode was a South African immigre to the USA. He passed away at a very
young age. A major contributor to the science and technology of modern
Electrical Engineering. If one were to make a list of the top 10 Electrical
Engineers of all time, Bode would be on it!

Oh... what I would give to have been able to sit in on those "Out-of-Hours"
classes in the winter of 39-40 or 40-41!

I'm still not having much luck confirming Jim's notion that the FAA routinely uses circular polarization at their VHF Comm sites.

Here in the Northeast, all the VHF Comm antennas I can find on local airport towers and on the area FAA Center building in Nashua NH are (obviously) vertically polarized.

Going beyond that observation, from a technical standpoint, wouldn't it be true that, even at a 45-degree bank angle (defined in aviation as a "steep turn"), cross-pol attenuation should only amount to 3-dB or so? (I could be wrong)

Also, isn't it true that a circularly polarized array would impose a gain penalty on all aircraft using vertical polarization--including those aircraft operating in straight and level flight? (I could be wrong again)

Given these considerations, I can't help but wonder if those Lindy antennas weren't being installed on FAA towers for 136 MHz WX satellite reception rather than for VHF Comm duty? That makes a heap more sense to me.

Anybody know the real deal??

45 degrees = 0.707 = 70% = -1.5 dB (?)

"dipole - See: dipole antenna, magnetic dipole, electrically short
dipole, folded dipole, half-wave dipole, Hertzian electric dipole,
Hertzian magnetic dipole, microstrip dipole."

"dipole antenna - Any one of a class of antennas having a radiation
pattern approximating that of an elementary electric dipole."

The IEEE dictionary goes even farther and says that common usage means
a current node at each end of a thin wire antenna. One wonders how a wire
ending in space could have anything but a current node.

It really gets hairy when one uses a 75m dipole on 10m. Is a 75m dipole
still a dipole when it is used on 10m? It has more electrical poles
than two and does not meet the definition of a "dipole antenna".

Here's one for you, Peter. If a dipole antenna is not being used,
is it still a dipole antenna?

> BTW... What does the dictionary say about "doublet"?

Synonym for dipole.

> the antenna. Right?
> 'Doc

Well, Doc,

It may be just an opinion, but I do believe it does affect, at least, the
efficiency of the antenna
as opposed to the coil turns down inside the mast of a SD. Those turns that
are down inside
the mast are decoupled at the fingerstock and become, in effect, a part of
the lower mast. I
believe, from some admittedly very unscientific experiments I have done,
that those turns that
are by-passed still have *some* RF on them, but, because of the jumper,
can't "do" anything
resulting in wasted power--kinda like back pressure in a car muffler. That,
I think, is why the
SD's work so well--much more RF is sent thru the system and out into the
ether instead of
muddliing around amongst jumpered turns. The experiment(s) I
mentioned--well, one of them--
was with some old Master Mobile coils I have laying around. I tuned one on
3920 (MFJ 259)
so that I had ONLY coil with no jumper, and another one (identical) with a
jumper. There *seemed* to be a little more efficiency with the unjumpered
coil, tho not by much, and the impedance value was different at the
feedpoint indicating (to me) that the coil with the jumper
was exhibiting more resistance (?????) than the one without. I then set
them up on higher freq-
uencies (40, 20, 15, etc) and got the same result.

Now, having said that, I know antennas WILL tune with wander leads, and also that I am not
a "master" at antenna theory. But I AM learning! LOL! I do not vouch for my very unscienti-
fic experiments; rather, I drew some conclusions from it that *seem* to make sense--to me
anyway. LOL!

This is where I get the most fun from ham radio--experimenting, trying out things, correcting,
and BEING corrected. That is how I learn and become better in the hobby. That, Doc, is
why I read your posts and the posts of other hams whose knowledge and opinions I respect.

Perhaps you've found them by now. I'm way behind with e-mail and
newsgroups. But if not:

I just bought a 51-Ohm thick-film resistor in a TO-220-style package
from Mouser to try it out. I'm pretty sure Digikey carries them too.
The catalog claims that it's "low inductance". It's rated at 35 Watts
when properly heat sinked.

My digital VOM says it's 50 Ohms, and the MFJ-259B says R=49 and X=2 at
146 MHz. I haven't fed it any power yet, but it looks promising.

If I remember correctly, they're available with ratings up to several
hundred watts.

Cecil,
Sure, it applies to dipoles, folded or un-folded, drooping,
inverted, vertical, horizontal, diagonal, even laying on the
ground. Especially if you're using coax for a feed line. The
same for if you're using ladder-line, it just doesn't matter as
much...

Plug your circuit into PSpice and run an AC sweep. There's a free downloadable student version if you are on a low budget. Then find the DB Magnitude option.

Alternatively, use Matlab's Bode command with your transfer function. That's what we are doing in my college electronics engineering courses.

You can also plot it out by hand by plugging in certain frequencies and calculating 20*log10(Vout/Vin).

You don't even need a transfer function to do that - just simple phasor analysis with Zc = 1/jwC and Zl = jwL.

>Hz and -50.1 dB at .497 Hz.
>
>Can someone tell me how you would draw the Bode Plot for this circuit?

Okay, here's the deal: For a second-order band-pass filter, the form
of the transfer function is

```
w0
-- s
Q
----------------
2 w0 2
s + -- s + w0
Q
```

From s^2 + 100 s + 100,000

w0 = 316 so that Q = 3.16

When you estimate a second-order band-pass filter's characteristics
using a Bode plot, each skirt will roll off at a first-order roll-off
rate: -20 dB per decade. But the Q of your system is greater than 1 so
that some "peaking" will occur near resonance. The effect of this
peaking is that the asymptotes of the skirts will be parallel to the
Bode estimates but _below_ where you might guess the estimates to be.
That is, at a distance far enough from the center frequency, each
skirt will roll off at -20 dB/decade but the asymptotes will be
somewhere below "first-guess" asymptotes that intersect the center
frequency at 0 dB.

There might be some rule to estimate how far below the first-guess
asymptotes the true asymptotes are, but I don't know what it is.

Regarding s = -50 +/- j312.2498999: Yes, that is correct. But look at
the form of the band-pass filter that I provided, above. Substitute jw
for each s term and notice that at w = w0 the denominator reduces to
(w0 / Q)s, which is the same as the numerator. Thus, at w = w0, the
gain of your filter is 1. At any other w, the magnitude of the
denominator is larger so that the amplitude of the filter is smaller.
So the peak of the band-pass filter occurs at w = w0, not at w =
321.2498999.

No, dipole just says there are two poles. It
doesn't say a thing about being equal, nor
does it say anything at all about feedpoint
or if it's fed at all. Moreover, in your original
post, you didn't even specify that your
dipole was an antenna. (I assumed it was.)
However, since you have no less an authority
than Peter Brackett agreeing with you I
suppose I should too. However, I won't.
Enlighten me Cecil; is an off-center-fed
dipole not a dipole? If it's not, then you have
a point.

I don't know how Hendrik pronounced it himself, and I have never met anyone with that surname to ask them. H. W. Bode was an Afrikaner from South Africa who immigrated to the USA. So it is probably a Dutch-like name. I am sure that he must have spoken with an accent.

That said... in my personal experience, universally everyone that I have heard pronouncing his name, have pronounced it as "bow dee".

Crazy:

I miss those Scratchi columns in CQ. They were popular back when Wayne Green was the editor of CQ. Scratchi was always the first thing I read when the issue arrived.

Today those columns would probably be considered not PC.

I forget now, did Hashafisti ever actually ever give any call letters?

Don't you mean that the intensity falls off as 1/r in the far field,
not the near field?

Thanks for the info. I have heard it pronounced that way many times
too. For what it's worth. In Circuit Analysis , 1991, by Allan D. Kraus,
page 742 footnote, "Pronounced Bodah, not Boad or Bodie". Since Dutch is a
Germanic language, I would think that an "e" on the end of a word or name
would not be pronounced like a long 'e' as in Bodee. Ratch

Rick, K1BQT wrote:
"---cross-pol attenuation should only amount to 3 dB or so?"

Antenna polarization is the direction of the voiltage (E field) vector.
If an aircraft`s inclination reduces the voltage vector by
1/sq.rt.(2), (0.707), the resulting current is also reduced by 0.707x.
Thus the power is reduced by 0.707 squared, or 0.5. So, the db loss is
3.

This statement was playing on my mind, so I decided to investigate.

A first-order low-pass filter with a corner at w0 will roll off at a
-20 dB/decade rate just like the upper skirt of the band-pass filter.
Since the question is "What is the rule for vertical offset of the
amplitudes?" I expressed a first order LPF as

```
w0
------
s + w0
```

This function can be nicely represented as a -20 dB roll-off in a Bode
plot. I took the ratio of the absolute value of the above expression,
divided it by the absolute value of the expression that I used in my
previous post, and then took 20 log of their ratio to get

```
|first-order expression|
20 log ------------------------
|second-order expression|
```

Then I substituted for s using s = jw and took the limit of the above
expression as w goes to +infinity. Using Derive 5 (a nifty program for
those who are lazy at algebra or calculus, available from Texas
Instruments Student Center) I evaluated the limit algebraically and
came up with this compact result:

```
20 ln |Q|
```

Yes, that's the natural log. So if Q = 3.16, the vertical offset of
the asymptotes is

```
20 ln 3.16 = 23 dB
```

There is only one field.

It is mathematically convenient for analysis to break it down into 2 or more fictional components. It's also useful as a source of something to argue about when there's nothing else better to do.

Come to think of it - the whole damn thing is just a mathematical fiction.

In fact, this is all patently obvious.

Anyone who has manually observed the amplitude output of (say) an RC Low Pass filter with respect to increasing frequency, must have noticed (unless they were unbelievably imperceptive) that attenuation begins gradually. It clearly does not instantly switch from no attenuation whatsoever, to a fixed attenuation slope at a particular frequency! From this it is blatently clear that a Bode plot is a straight line simplification of reality.

Bob.

4250. WANTED: how to modify AA battery holder for handheld to accept 9V batteries

There was a QST article a few years ago on how to modify a AA battery holder to accept 9V batteries. It involved cutting parts of the plastic out and rewiring the inside of the unit. Has anyone here done anything like this?

I have an old FBA-15 AA battery holder for my Yaesu FT-50R that I replaced. (It had some bad contacts, and while I could revive it by placing aluminum foil in the appropriate places or scrubbing the metal contacts with sandpaper, I wanted something more reliable.)

I still have the FBA-15. What tools do I need to rip out the plastic and metal "walls" inside so the holder will accomodate a 9V battery? How would I secure this 9V battery inside the holder?

Bode pronounced boadie, is certainly the English way of pronouncing it.
As in "Ode to Joy" . But H. Bode was probably of Dutch extraction, so it is
probable that his name would be pronounced in a German like fashion as
Bo-dah. I am not saying that you are certainly wrong, but it is a good
possibility that you and the civilized world are not right. A name is
tricky, so only those acquainted with him or know someone that was can be
certain. Ratch

Heh, heh... as Bart Simpson would say... cool your jets man!

Actually, although I am a US citizen, by descent I am a "colonial boy", born and educated in Canada, educated in the ways of the British Empire, I learned to spell the British way, and to speak the American way. I find that MS Word's spell checker keeps my roots unoticed in my adopted land.

Even though I am a US citizen, I have always lived in the South. In particular: Florida, Georgia, Alabama, North Carolina, and I consider myself to be a Southerner not a "Yank". I resent being called a "Yank", since we Southerner's don't have no truck with "damm Yankees".

Since you are clearly closer to the "mother tongue" than I, I will certainly defer to your clearly superior command of English and recommended pronunciation of Bode. Of course as an imigre from South Africa to the USA, H. W. Bode's native tongue would most likely have been Afrikaans and not English, and so you will excuse me if I remain skeptical of your suggested pronunciation.

BTW... we "Yanks" are not the only ones that assume that our way is the only way... here's a little anecdote from my personal travels in Europe and the British Isles.

One fine foggy morning, as I was driving onto a ferry to re-cross the channel from Britain to France, in a left had drive rental car, which I had rented in Madrid Spain, I found myself directly behind a right hand drive British bus clearly heading for the Continent where no one is a native English speaker. On the rear of that bus was a sign, *only* in English that read, "Caution, right hand drive bus."

What??? Leave it to the British to assume that all others will understand English!

Y'all enjoy the rest of the day now, heah,

From my experiences "over there", my guess is it should be pronounced
" Bow' duh " (accent of first syllable).

And I certainly don't know what Kevin would know about civility ;-)

According to the IEEE, when one says, "dipole antenna", with no additional qualifiers, one is understood to be referring to a center-fed one half wavelength resonant thin wire dipole antenna. For any other kind of dipole, a qualifier must be given. Thus, an off-center-fed dipole antenna is not the same thing as a "dipole antenna". I wasn't 100% correct myself.

microphone.
This is NOT A CW PULSER
which key's and unkey's in the CW mode . This works in SSB MODE.
Key your mic push the
moumentary switch to activate the pulser and Tune Away.
Let me give you an
example.....
Tuning a Dentron Clipperton
L amp. with a Icom 751 A radio, Pulser installed in a Ten_tec 705 mic.
set radio to full output on
desired frequency SSB MODE into a resonate antenna of course.....or
dummy load
Set amp to proper band
settings
Key mic and push Pulser
button..... watch watt meter it will show aprox 100 to 200 watts out
when tuned to peak output
using Pulser....Remember don't key too long 10-15 seconds
Then check output using
voice.... It will be full Output 1200 watts
See How easy that was....
The amp loved it and now your ready to talk at Full output.
The same tuning is used to
tune a tube type rig also.

> much...
> 'Doc

The point is that it doesn't matter at all with open-wire fed dipoles. The open-wire line, with its 600 ohm characteristic impedance cannot tell the difference between a 1/2 wavelength resonant dipole with a 60+j0 ohm feedpoint impedance and a one wavelength anti-resonant dipole with a 6000+j0 ohm feedpoint impedance. The SWR on the open-wire line is identical in those two cases. That's the point that I am continuing to try to make.

For a 60 ohm antenna the SWR will be 600/60 = 10:1
For a 6000 ohm antenna the SWR will be 6000/600 = 10:1

One cannot tell those two antennas apart at the transmitter end if one cannot see the antenna and doesn't know the length of the feedline. If one cannot tell the difference then it is an old wives' tale that a one wavelength dipole is a problem. With open-wire as the feedline, there is absolutely no reason to worry about avoiding a one wavelength dipole.

Damn you're good. It actually makes sense since (at 45 degrees) the other half of the power (the missing half) should be showing up on the horizontal plane. Symmetry and all that. Thanks for correcting me.

I don't want an antenna on my roof and my attic trusses prevent me from putting it up there (and aiming it at Chicago) so I am left with a set top antenna. Could/would someone recommend something good? I have a RS set now that is great at 9 and up but is very weak on 2, 5 and 7. Any help would be appreciated?

In the '60s there was an artist, Vaughn Bode (RIP), who drew underground
comics, very popular amongst the stoners. But nobody knew how to
pronounce
his name either, and when he signed his art, he put a little accent mark
over the e. And none of the websites dedicated to him seem to have any
indication of how it's supposed to be pronounced. I'm a iggorunt
Murrican, but I can go with "rhymes with abode, code, lode, mode, node,
rode" etc.

It's exactly the same case as Bob Moog of synthesizer fame- people constantly mispronounce his name as if it starts with a "cow noise" - MOOO! But that is wrong, it is pronounced "moag" with a long O. And my name is constantly spelled incorrectly, even as I am spelling it out letter for letter to someone who is writing it down. They must have some sort of genetic program where the hand darts out and inserts "c" and "z" here and there.
A sure way to earn a black mark with a man is to constantly wreck his name.

Yep.

On my first day of college electromagnetics class, I asked the professor (Carl T.A. Johnk) what an electromagnetic field was, that being a question I'd never gotten a satisfactory answer to during my military technical school training. He said that it's a mathematical construct we use to deal with certain phenomena that we can measure. And I see that in the second paragraph of his book _Engineering Electromagnetic Fields and Waves_, he says "A field is taken to mean a mathematical function of space and time."

That's because if you pronounce it aloud, it probably sounds like "Sgt.
Schultz" from Hogan's Heroes. Care to share the etymology? Mine is
pronounced "Gryce," and is probably derived from the German "Greis"
or "Greiss." My Dad (RIP) used to say, "Grise, rhymes with nice."
Of course, on an international NG, that doesn't work, because of Nice,
France. Maybe I should say, "Rhymes with "Gneiss." :-)

Probably the most popular is the MFJ259 from MFJ Enterprises (www.mfjenterprises.com). It covers HF and 2 meters. I use the heck out of mine. It is a bit of a battery hog, so I keep my 12v wall wart handy and use it when I can.

They have a new one, called the MFJ 269, it adds 440 MHz to the unit. Well worth the few extra bucks, even if you only wind up using it once.

I picked up mine used, you can probably find one at a hamfest for a decent price.

BlankHi Ron,

Just as a follow up, can you get to your attic? I've known folks who've gotten very good results putting a simple dipole up in the attic.

Another possibility, even though you are in a "no outside antenna" area, you might consider putting a dipole just under your roof eave. You can use something like electric fence stand off insulators, and u-nail the coax to the eave and down the wall. Place it in the back where no one is likely to see it. I seriously doubt anyone would ever notice (especially in the back of the house) and if they did, you can claim it's for hanging Christmas lights on. (Get some wire same color as the house, makes it even less likely to be seen).

ARRL sells a book on "stealth" operating, that I'm told is quite good. I had the earlier version when I lived in an apartment, but now that I'm out in the country I've been growing my own antenna farm.

Ahem! Speaking as a resident of the backwoods of Southern California,
some years ago we were contracting with another company to build an
air-to-ground communication system. The UHF signal could possibly be
blocked/attenuated by the wings, etc. of the aircraft as the aircraft
varied its attitude. A Brit from the other company (who, by way of
sound judgment, was applying to become an American citizen) talked of
how "the signal might be wooded." This drew a lot of stares from
around the table. We explained that "the signal might be shaded" might
be a better choice of words. In a display of further sound judgment,
he agreed.

Bill, N3WK wrote:
"Don`t you mean that intensity falls of as 1/r in the far field, not the near field?"

Chip was using power, not volts per meter. Volts per meter decline as 1/r in the far field, but power declines as 1/r^2. That is expressed in the famous "inverse square law". Double the distance from the source in the far field, and the signal drops by 6db, not 3db. Chip got it right.

Arnold B. Bailey has a graph of "Free-space received power showing near and far fields" on page 211 of "TV and Other Receiving Antennas".

The slope of the decline in received power is increasing as the reactive fields play out, from 0.1 wavelength out to 3 wavelengths. From 3 wavelengths out to 10,000 wavelengths where the graph ends, double the distance gives a 6db increase in signal loss on the graph.

Point is, loss per unit distance falls less rapidly in the near zone than in the far zone, as Chip says, because the total field is being supported in the near zone by the reactive field.

Bailey says the radiation field which survives into the far field decays as the square of the distance. The reactive fields are strong in the near zone within a few wavelengths of the source. These are soon gone for practical purposes.

Best regards, Richard Harrison, KB5WZI

J. Harvey wrote:
"It actually makes sense (at 45 degrees) the other half of the power (the missing half) should be showing up on the horizontal plane."

Old Pythagoras, 569 bc - 475 bc, figured out that the square on the hypotenuse of a right angled triangle is equal to the sum of the squares on the other two legs.

A hypotenuse on an angle of 45 degrees with the other two sides (legs) of a right angled triangle has a ratio of 1.414, the square root of two, with the other sides, valued 1 and 1.

This relation could also be expressed as a hypotenuese value of 1 with horizontal and vertical components (legs) of 0.707 and 0.707. This is accomplished by simple scaling (multiplying all sides by 0.707) and setting the attitude of the triangle.

That`s how we figure we get 0.707 volts when we rotate an antenna by 45 degrees to the polarization existing in a field of 1-volt.

Best regards, Richard Harrison, KB5WZI

Is it urban legend time? A group of American reporters, back in the
days of the communist Soviet Union, was visiting a factory. The soviets,
of course, were singing the praises of the communist system, while
showing
off the great productivity of the factory workers. From each according
to his ability to each according to his needs, and all that. One
reporter
asked, "Well, what would happen if some guy just decided to stop
working and loaf, while collecting his benefits?" Through the
interpreter,
the answer was, "Then he would be shot." There was such shock and
consternation amongst the Americans, that some discussion ensued.
Finally,
the interpreter said, "Oh, he would be fired."

Signots wrote:
"I have a RS set now that is great at 9 and up but is very weak on 2, 5, and 7."

Assuming an outside antenna would receive low-frequency channels well, and that the TV set is OK, there may be two problems with Signots` low channel reception.

Channels 7 and 9 are in the range of 1,7 to 1.5 meters in wavelength. Signots` dividing line between good and bad reception falls between these channels.

The signal must penetrate Signots` structure to reach his antenna. That is probably the first problem. The structure is a sieve that lets in the shorter wavelength signals but blocks the lower channels.

The second problem may be an indoor antenna which favors the higher channels.

The first thing to try is placement of his antenna tn a window which faces Chicago.

Best regards, Richard Harrison, KB5WZI

First of all, Scratchi was published for many years under Cowan before Wayne Green became editor of CQ.

Second, while I remember a number of plays on racism, there were a number of technical faux pas described which were funny without race reference. The IPOIO was one of them, and the resistance hook-up wire in the home built receiver was another. So was the time he turned out to be resonant on a harmonic which caused TVI and they wrapped him in wire and bypassed him to ground. What's politically incorrect about that? Maybe he could be a red neck w4 instead of Scratchi, if you're really that sensitive? Or better yet an Iraqi spy or a space alien? As far as I know, those last two are still fair targets.

Message-ID: <ar838u4kvgpkl5d8rthbullkc8k6avqkv2@4ax.com>
Source record: 147469

This may be of interest to people setting up antennas using a compass. Magnetic North and True North are not always the same. If you were calibrating a beam heading using magnetic north as a reference on your readout you could be in error. The declinatin or correction factor can be significant. A case in point is my location in Nova Scotia. True North and Magnetic North are different by 20 degrees! If you wish to know the declination for your particular part of the world a good place to visit is http://www.geolab.nrcan.gc.ca/geomag/e_cgrf.html
Hope this is of interest to antenna buffs. Thanks for reading.

...But who says that to have a good experience in ham radio you must
have a large beam antenna for HF on a tall tower with slopers in
various directions?

The hobby is full of other things you can do, from participating in
club station efforts, to home brewing, to portable or mobile
operation, training other hams, and so forth.

CC&Rs are serious impediments, but they're not the end of this hobby.

Reg wrote:
"---the whole damn thing is just a mathematical fiction."

Well, real force is exerted between the rotor and stator of a motor in doing real work. There is no electrical conduction involved between the motor parts. The magnetic force field is the link between these motor parts.

You are probably reading from a CRT. The light on the screen is produced by electrons striking the screen with sufficient force. That electron acceleration is produced by another invisible linkage, the electrostatic force field within the CRT.

Likewise, lightning produces real amps of electricity flowing through the atmosphere, but kilowatts of real electrical power can flow through the atmosphere with no volts or amps traveling in the atmosphere at all. It is only the fields produced by those volts and amps which link the sender and the receiver.

Best regards, Richard Harrison, KB5WZI

|Wes, attend a Worldradio field day event and look for 80ish year old hams
|with original W6 calls working on antennas. You will narrow the field
|considerably.

Not having been nor intending to go to a Worldradio anything, I can't use that tool. The only W6 that I know that might fit the bill is W6UYH. I lost track of him at Hughes a long time ago and QRZ.COM reports him in San Manuel, AZ. But I doubt it is he as his writing was accurate and insightful.

As to "real" Sterbas:

http://www.qrz.com/callsign?callsign=NAME&search=sterba

Take a look and tell me which of these folks fit the bill. I think we can eliminate (figuratively speaking) the woman right away.

And it you want to spell it "Sturba" then LU6EEV must leap to mind.

Regardless of who "Kurt" really is, let's hope the unwary don't take anything he writes seriously.

George et al:

Hey! You guys are much older than I... heh, heh... My recollection of Scratchi only goes back to the Wayne Green era of CQ.

Thanks for reminding me of the meaning of IPOIO.

Ahhh... to experience the "innate perversity of inanimate objects", how well I remember the ecstasy of that first experience myself.

IMHO, except for experiencing the innate perversity of a wife "IPOAW", there is nothing better for the growth of character and of the soul. With apologies to my dear Mary of course!

I believe that, the then Poet Laureate of Great Britain", Rudyard Kipling first coined that eloquent phrase around the turn of the last century, when he wisely specified that experience as one of the mandatory requirements for qualification as an Engineer in his famous oath "The Calling of an Engineer".

As to the current status of political correctness, well I was almost lost in the wilderness of looking for buts for humor, since our "liberal" consort had almost run us out of grist for that mill, but now, thanks to the evil stupidity of bin Laden and his ilk, we have Al Quaeda and Taliban to make fun of.

Jerry, I use an HF6vx here, and it works fine for me.

The 75 ohm co-ax section is there to transform the 100 odd ohm impedance @
20m to approx 50 ohms.

Mine has excellent match on 10, 15, 20, 30, 40 & 80m. on 12m it's approx
5-6:1 and on 17m approx 6-7:1 but I just tune into the feeder with an ATU.
In fact, I use an FT-102 radio with tube PA which is quite happy to load
into the antenna on 12 & 17.

I suggest that you check your electrical connections at the feedpoint, as
the only time I've had high SWR problems the cause was a poor connection.
Also check that there's good connectivity between the tube sections and
coils etc.. bad connections here will definitely cause problems.

As an aside, when I first installed the antenna, I had no radials at all and
the antenna worked fine on all bands except 80m, where I couldn't get the
SWR to less than 2.5:1 or so.
I added 4 40ft buried radials which completely solved the problem, SWR on
80m now 1.2:1 with bandwidth of approx 75KHz at 2:1 points.
The radials all run out in the SW,W & NW compass headings, due to the
topology of my back yard, it's not possible to provide radials in the
direction of Africa/Europe/Scandanavia but I have no problem working those

areas.

But I do have good wet ground here, and live within 500 meters of the sea shore here in South Wales. The mounting pole always has water in it, even in summer.. it goes down about 2m depth.
The antenna is located approx 5ft from a metal clad building, which is approx 20ft x 15ft and approx 7ft from a 25ft pole which hosts a 6m 5ele monobander and rotator.

I'm very pleased with the performance of the antenna, it even cracks pileups sometimes with 100-150w that the FT-102 provides. Many operators are surprised when I tell them what the antenna is.. a ground mounted vertical.

As an aside, does anyone here have the mechanical details of the 12 and 17m resonators? I'd like to make them myself, as they cost a lot of money here for a bit of aluminium tubing! Ideally, I'd like the diameter of the coil, number of turns and dimensions of the capacity strips.

Hope this helps!

>

Jerry, I use an HF6vx here, and it works fine for me.

The 75 ohm co-ax section is there to transform the 100 odd ohm impedance @
20m to approx 50 ohms.

Mine has excellent match on 10, 15, 20, 30, 40 & 80m. on 12m it's approx
5-6:1 and on 17m approx 6-7:1 but I just tune into the feeder with an ATU.
In fact, I use an FT-102 radio with tube PA which is quite happy to load
into the antenna on 12 & 17.

I suggest that you check your electrical connections at the feedpoint, as
the only time I've had high SWR problems the cause was a poor connection.
Also check that there's good connectivity between the tube sections and
coils etc.. bad connections here will definitely cause problems.

As an aside, when I first installed the antenna, I had no radials at all and
the antenna worked fine on all bands except 80m, where I couldn't get the
SWR to less than 2.5:1 or so.
I added 4 40ft buried radials which completely solved the problem, SWR on
80m now 1.2:1 with bandwidth of approx 75KHz at 2:1 points.
The radials all run out in the SW,W & NW compass headings, due to the
topology of my back yard, it's not possible to provide radials in the
direction of Africa/Europe/Scandanavia but I have no problem working those

areas.

But I do have good wet ground here, and live within 500 meters of the sea shore here in South Wales. The mounting pole always has water in it, even in summer.. it goes down about 2m depth.
The antenna is located approx 5ft from a metal clad building, which is approx 20ft x 15ft and approx 7ft from a 25ft pole which hosts a 6m 5ele monobander and rotator.

I'm very pleased with the performance of the antenna, it even cracks pileups sometimes with 100-150w that the FT-102 provides. Many operators are surprised when I tell them what the antenna is.. a ground mounted vertical.

As an aside, does anyone here have the mechanical details of the 12 and 17m resonators? I'd like to make them myself, as they cost a lot of money here for a bit of aluminium tubing! Ideally, I'd like the diameter of the coil, number of turns and dimensions of the capacity strips.

Hope this helps!

> the famous "inverse square law". Double the distance from the source in
> the far field, and the signal drops by 6db, not 3db. Chip got it right.

Here's what he said:
"You can look at the near field as the volume (not area) within which
the
intensity falls as 1/r (where r is distance from radiator) and the
far field
as the volume--extending out to infinity-- for which the intensity
falls as
1/r^2. All in free space, of course."

My question was with his "1/r" variation of "intensity" in the near
field.

Usually, "intensity" implies field intensity, as in field strength.
Second, he's obviously talking about radiation, not received power,
since he breaks infinite space into 2 volumes according to distance
from the radiator. But why don't we let him respond rather than
guessing what he meant?

Then, neither power density or field intensity fall off at 1/r in the
near field. Power density for an aperture oscillates in the near field
but the envelope is relatively constant. The field strength for a
short dipole consists of two quantities, one in 1/r, 1/r^2, & 1/r^3;
the other in 1/r and 1/r^2. Neither of these fall off at 1/r. Power
density for a short dipole varies according to the cross product of
these two quantities. No way this product is going to be 1/r. He got
the near-field part wrong either way.

> From 3
> wavelengths out to 10,000 wavelengths where the graph ends, double the
> distance gives a 6db increase in signal loss on the graph.

No argument.

SWR is associated with the amount of power an antenna will
accept. What are the other reasons that a 6000 ohm one
wavelength dipole won't work as well as a 60 ohm one half
wavelength dipole?

>Jake Brodsky, AB3A mailto:frussle@erols.com
>"Beware of the massive impossible!"
Hi all,
I agree with the above post, there are a lot of things that can bring
enjoyment from the hobby other than large antenna arrays. My fellow
GMDXA member, N9XX, does just great with a very short vertical and
attic antenna. So, that said, yes, it's great to have a big array.
My question is, why move into an area that has restrictions? Is the
area a status thing? Is it a wife driven thing? Is there positively
no other option?
When I was looking for a newer home, I took the time to sit down with
my wife and make a list of "must have items". We each had our list
and discussed the combinations that would satisfy us both.
Her list,
Ranch style
Dining room

Family room
Fireplace
First floor utility room
Close to freeways access/park and ride lot

My list,
Everything on her list
Underground utilities
1/2 acre or more with trees to string wire thru
Enough room to put a tower up
Preferably on top of a hill for line of sight work
NO CCR's or ANY OTHER RADIO RELATED RESTRICTIONS

Now we had our criteria for a house and locations to search (I used a topo map). I told my lawyer (never use a real estate agent) what I wanted in terms of bid/buy offers and he wrote them up. They always included a paragraph on CCR's and restrictions. If they were enforceable in any way after the offer was accepted the offer was null and void. This was in case I missed something in my research. Oh yes, research, I did plenty of that, from asking the mailman and random people in the area how they liked living there to driving/walking the area looking for good and bad things. Next was researching schools, local government, past and any pending assessment issues and operating out of the car near the prospective site. At the closing, my lawyer instructed me to cross out any CCR's and restrictions in the document and initial them as not applicable. He instructed me it is better not to buy if these changes are not accepted. Now this was an older subdivision and I have never had a problem with any of the crossed off parts of the contract.
Now that I have said alllll of that, whew! It appears to me that if you want to pursue amateur radio with big arrays, then you need to complete your research before you buy, not after. Maybe there are areas that span 100's of miles where CCR's are the norm, I don't know personally of any, but what the heck do I know anyway.
Yes it was a lot of work to do all that for multiple sites, but it was worth every minute of my on air time during the past 19 years here!
Thanks for taking the time to read this and of course it is all only MHO.
Dan

I've rambled enough, back to the rocking chair. ZZZZZZZZZ

What kind of antenna or load are you using the 9:1 balun with?
If your 450 ohm ladder-line is carrying an SWR around 9:1, you
don't need a 9:1 balun. In fact, if the 450 ohm SWR is not 1:1,
you will never see 450 ohms.

"Richard Harrison" wrote eloquently about fields:
> Reg wrote:
> "---the whole damn thing is just a mathematical fiction."
> <snipped only for brevity - refer to original if required>

Reg is correct. You saw my posting about Richard Feynman's Nobel Prize ?

"...there is no field..."

However, electromagnetic fields are a very useful 'mathematical fiction' (at least in the far field). But, the part about the near field and its 'Intensity' being proportional to '1/radius' (I=1/r in the near field) seems problematic.

First, let's review the far field I=1/r^2 rule of thumb: The surface area of a sphere goes up as the square of the radius. That means that in the far field, where I=1/r^2, there is a constant energy at any radius (not per unit area, but summed over the entire surface area of the sphere). Obviously, the energy has to get from A to B by way of spheres (being spheres since c is constant). Therefore, the I=1/r^2 rule of thumb adheres to common sense conservation of energy. Therefore, the I=1/r^2 far field rule of thumb is okay.

Now the near field: According to the I=1/r rule of thumb (in the near field), the energy contained in the various imaginary spheres is not constant. As we approach r=0, the energy in each sphere is dropping towards zero. This is because the surface area of the sphere is dropping towards zero much faster (SA=1/r^2) than the intensity (I=1/r) as we approach r=0.

Perhaps the energy is hidden in "excess" E or H fields and not "registering" on the combined EM intensity ? This makes measurements in the near field very problematic ! Does your probe respond to E, or H, or both, or some mix depending on orientation, or "only EM" ?

And nobody has yet explained the transition from the far field (I=1/r^2) to the near field (I=1/r). It obviously doesn't "shift gears" instantaneously.

And the I=1/r rule of thumb doesn't hold water when r approaches zero since the intensity at r=0 is infinite (this also applies to I=1/r^2 unfortunately).

This whole 'near field' I=1/r thing is a mess. I=1/r is obviously wrong on many counts. It might be true at some particular radius, but that is useless as a rule of thumb.

No wonder even the experts can't seem to agree.

And the fact (the Nobel Prize winning fact!) that it is all a mathematical fiction anyway...

Sigh...

:-)

Erd��s is spelled with ".
In the common windows western character table " is an o with two
dots over it.

" is pronounced like the first wovel in these english words:
first, sir, purly, colonel, heard, girl, curling..

English can be a very confusing language to other nationalities
because the same sound can be spelled in many different ways,
and the same letter can be pronounced in many different ways in
different words.

If Bailly is a french name, and it looks like that, it should
probably be pronounced Bay-ee, with the tension on the ee and
also with a raised tone on the ee.

Roger

Hello,

My answer is accurate and complete in the context it was presented.The words I used, and what I said was, and is, well-known, accurate, and so on. You may debate it if you wish; I didn't invent/define Fraunhofer and Fresnel regions:-) Why pose it as my issue?

If you wish to discuss higher order content, then that's fine. Boundary conditions are always interesting, although I don't seem to recall the question, as originally posed, being made in that context.

(Here's an interesting boundary condition problem: let's say you could drill a hollow sphere at the center of the Earth. Describe what force(s) you would feel, if you are reasonably point-like. Now use this info to see how a hollow shell of matter would affect time dilation. This is known as the Mother-Baby Paradox, posed in the mid-70's by Thomas Gold.)

It may be a useful to check to see if our original poster feels he has enough information though, as these issues of minutiae seem, to me, far beyond the nature of the question posed and the type of infoirmation desired.

73 and Enjoy,
Chip N1IR

Message-ID: <hssg8.86568$JZ.11771771@news20.bellglobal.com>
Source record: 147494

An antenna which closely meets this idea is that of our Baby Boomer Quad (Multi-Banded). Basically the antenna is about half the size of a normal quad with slightly less performance.

This allows for some interesting design features to be added to the antenna.

1. Multi-banded (10-15-20m)
2. Heavy Duty
3. Portable (Easy assembly and disassembly). Can be assembled in one hour.
4. Great Performance, slightly less than a full size quad.
5. Small package.

The best place to go and start searching antenna information is that of W4RNL site at www.cebik.com/radio.html

Our site is www.degendesigns.com home of the Baby Boomer Quad.

If you wish to contact me info@degendesigns.com

> uses circular polarization at their VHF Comm sites.

And Jim is basing his comments on the advice of two FAA avionics inspectors, one in San Diego, and one in Reno, who separately and independently told me that the FAA standard was for some sort of circular polarization. I freely admit to never designing or installing any FAA facility ground antennas. All the ground antennas I've ever designed and/or installed were good old ground plane or J antennas on small airport unicom and FBO radios. My bag is the airborne antenna, not the ground antenna.

> Going beyond that observation, from a technical standpoint, wouldn't it be true
> that, even at a 45-degree bank angle (defined in aviation as a "steep turn"),
> cross-pol attenuation should only amount to 3-dB or so? (I could be wrong)

45° is only "steep" in the private pilot test. In commercial and above, 60°
is the standard steep turn. And I agree with the other posters that at 45°
you are crosspolarized by 3 dB.

>
> Also, isn't it true that a circularly polarized array would impose a gain
> penalty on all aircraft using vertical polarization--including those aircraft
> operating in straight and level flight? (I could be wrong again)

Yes, but the gain penalty is constant at any flight attitude, which was what the designers were trying to achieve (according to the aforementioned inspectors).

Jim

Whenever Reg makes one of his provocative postings, I can't
help thinking of George Bernard Shaw's statement: "If you do not say anything
in an irritating way, you may just as well not say it at all, since nobody will
trouble
themselves about anything that does not trouble them."
Does anyone have a reliable idea of what constitutes a "mathematical
fiction?"
Was Michael Faraday perpetrating a fraud when he proposed using
the concept of a field to think about electromagnetic phenomena? And what
about
Maxwell? Was he aiding and abetting a criminal conspiracy when he clarified
and
expanded Faraday's ideas? Why is the study of electromagnetics still taught?
Perhaps
Reg will enlighten me.

Hmmm..

I seem to recall posting a short bit ago.

IMHO we've exhausted the useful info on this question.

If anyone would like me to suggest some Fraunhofer/Fresnel zone references I would be most happy to do so via e-mail. It is an ancient and well- explored subject at this point.

Frankly, there seem to be a couple of flamers here, and that's outside of my interest.

With Best Regards,
Chip N1IR

"Tdonaly" rhetorically asked:
> Was Michael Faraday perpetrating a fraud when
> he proposed using the concept of a field to think
> about electromagnetic phenomena? <etc.>

The various widely-accepted field theories work fine as long as you stay
away from those pesky and annoying boundary conditions...

...of course, science is often progressed by a close examination of those
exact sort of pesky and annoying boundary conditions ('...riding on a light
beam...' and all that sort of thing).

PS: I keep thinking that 'Tdonaly' must be some sort of Japanese name... :-)

J. Harvey wrote:
"First let`s review the far field I=1/r^2 rule of thumb:"

That is a problem because intensity is sometimes taken as volts per meter and is sometimes taken as watts per square meter. The definition being used needs to be stated. Also, I=1/r^2 is true, with a suitable constant to define units and if I is intensity in watts per square meter, not current in amperes.

J. Harvey wrote:
"Now the near field: ---As we approach r=0, the energy in each sphere is dropping towards zero."

The 1/r or the 1/r^2 are rates of energy decline. As we approach r (the distance from a radiator) =zero, the energy in each sphere is NOT dropping towards zero.

I got an ear burnt black from contact with such an r-f energized wire.

Attenuation of a radio wave primarily depends on its distance from the radiator.

There is a definite relationship between the input power to a given antenna and the electromagnetic field it produces.

We have a reactive field which collapses back into the antenna on each alternation of the r-f. This field fades in a very short distance and is nearly proportional to the inverse square of the distance.

We also have a radiated field which does not return to the antenna and goes on and on into space if not blocked. This field fades as most everyone knows, in terms of volts per meter, inversely with the distance.

Best regards, Richard Harrison, KB5WZI

4315. Coaxial choke and G5RV

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-03 18:38:05 UTC
From: kg4pss@arrl.net
Message-ID: <a3866922.0203031038.544a2347@posting.google.com>
Source record: 147500

On a previous post regarding G5RV's, a suggestion was made to make a choke out of coaxial line (along with few other suggestions ;-).

I have found that I have a small surplus of RG-6, and I was wondering if it were possible to use this (75 ohm)as a choke between the 50 ohm coax and 450 ohm window line? If so, what would the correct dimensions be? Primary use will be 100w on 75/80/40/20.

Thanks in advance for your insight.

Allen

If we define things that exist only because Homo sapiens exist,
then every concept is a "fiction" (assuming that only man is
capable of concepts).

For instance, there is a growing awareness that time has no
independent existence, is truly relative to change, and is
merely a mathematical model invented by man to keep track
of change.

For 75m, take a 2 liter pop bottle and wind about 20 turns on it.
That will probably work all the way to 20m.

I think you know more about that canyon than I will ever do, so
I'll pass on that one.

But to get back to the subject, Bode is pronounced Bo-de in
dutch, german, swedish, and most european languages.
It rhymes with modem if you cut away the last m.

I have never even thought of the pronounciation of Bode as
rhyming with "load" before this discussion reminded me that it
is the most likely one in english.

I'm afraid that wording might mislead some people. The impedance of an antenna or the SWR on its feedline have nothing to do with how much power the antenna will "accept". It does, however, affect how much power can be delivered to it by a fixed-impedance source.

I can get just about any antenna to accept virtually all the power from my rig. All I need is an impedance matching network to enable the rig to deliver the power to it.

Guess I should have said, "SWR is associated with the percentage of
forward power an antenna will accept". But my question still stands.
Why won't a one wavelength dipole work as well as a 1/2 wavelength
dipole if the SWR is the same?

> depending on orientation, or "only EM" ?

There's no problem with conservation of energy. In the far field, the E and H fields are in phase and a fixed ratio, so that you can infer the power or energy from either the E or H field strength. In the near field, the E and H fields aren't necessarily in phase, nor do they have a fixed ratio. So either field can vary in virtually any manner without involving any "hidden" energy. It's true that near field measurements are harder to make, because you do have to measure both the E and H fields, and their relative phases, to find the power at any given point. In the far field, all you need is the magnitude of one of the fields, and you know the rest.

>
> And nobody has yet explained the transition from the far field (I=1/r^2) to
> the near field (I=1/r). It obviously doesn't "shift gears" instantaneously.
> . . .

I'm not sure what "explanation" is needed. There's one total field. When you get far away from the source, it has certain simple characteristics (fixed E/H ratio, 1/r decrease in field strength, planar wave characteristics) that make it easier to analyze, and which we call the far field. Where this "begins" depends entirely on how accurate you need your simplifying approximation to be. It's just the same as observing that the square root of (1 + x) is about equal to 1 + x/2 for small x, and asking at what value of x the "transistion" occurs.

Source record: 147511

NEWLY AVAILABLE Program "ADDALOAD.exe"
======================================
A random length antenna wire may be made resonant at a particular frequency
by inserting either a coil or capacitor at any position along its length.
For overall wire length, wire diameter and location of the loading
component, the program computes either C picofarads or L microhenrys
depending on sign of the required loading reactance.

Greatest wire length accepted is 1 wavelength at the resonant frequency.
Results apply either to a vertical antenna wire or to both halves of a
centre-fed dipole.

The program has an educational facilty to slide the loading component along
the wire while observing how it changes value and type.

Download from website below program ADDALOAD in a few seconds and run
immediately.

A rallod?

AFAIK, in UK we pronounce the name to rhyme with 'bowed', but I suppose
a bowed plot should have curvilinear axes.

I really don't think there is a serious problem with the pronunciation
of names, unless you are addressing the person him/herself, when it is
courteous to be correct. It is also possible to over-egg the pudding;
the classic example is 'Don Ki-hoe-tay'. The Don lived well before the
lisping king of Spain whose impediment created modern Castilian
pronunciation. He probably called himself 'Don Keyshot', as reflected in
the modern French version of his name.

Often, the only way to know how to pronounce a name is to ask the
person or a close friend. Neville Thiele, he of the eponymous
loudspeaker parameters, pronounces his name differently from both
English and German conventions - he says 'teal'.

If you insist on accuracy, try 'Bailly' (astronomer) and 'Erdo"s'
(mathematician), where 'o"' is the best I can do in ASCII for an 'o'
with a Hungarian umlaut.

>
> ...the energy in each sphere is NOT dropping towards zero.

Of course it isn't !! It is just that the I=1/r rule of thumb implies that it does as per the simple relationship between 1/r and 1/r^2. This is my Main Point - it was a strawman argument to show that the I=1/r rule of thumb is obviously flawed. I wouldn't trust it. Seems to fall apart at every seam. Obviously, there is a lot more going on in the near field than simple I=1/r relationships.

4331. What do you recommend for HF DX

Source record: 147515

I made a lot of antenna's 1/4 wave verticals for 40, 30 , 20, 17 meters
etc. and have a lot of isolated chickenwire and other wires under it. Also
the ground is polder land and wet.
It works fine but changing freq. I have to put down the antenna and make
another 1/4 wave.

I also made a lot of deltaloops/loops,dipoles, edz etc. with ladderlines in
the past but the verticals worked best for DX.

As I am tired of changing the ant. what would be (nearly) as good or better?

Pls advice:

1. Butternut (HF6V or HF2V)... Hustler (6 or 5BTV.) Sigma 5 vertical or
other vert.
a. Ground mounted or b. Roof mounted (40 feet high)
2. Auto tuners SGC or LDG ?
3. Balun MTFT etc 1:10
4. Should I keep what I have as everything else is compromise?.
5. Others...

I would hazard a guess that EVERYONE is in agreement that there's no problem with conservation of energy !!!!! Good grief...

PLEASE NOTE that when I put up a strawman argument to demonstrate the fly in the soup, it doesn't mean that I agree with having the flies in the soup !

Of course energy is conserved - but how does that jive with 1/r ? The I=1/r rule of thumb (taken as written) **does** imply that energy is being hidden (or at least misplaced), most certainly as per your rational explanation below. Therefore, this I=1/r rule of thumb for the near field is obviously incorrect, incomplete and perhaps dangerous. People might start to believe it...

> In the far field, the E and H fields are in phase and a fixed ratio,

> both the E and H fields, and their relative phases, to find the power at
> any given point. In the far field, all you need is the magnitude of one
> of the fields, and you know the rest.

If you read what you just wrote (just above) and what I wrote above (near top), you will find that we are in complete agreement. My points were framed as rhetorical questions, yours are excellent answers to those rhetorical questions.

The near field sure is a whole lot more complicated than I=1/r - isn't it !

> > And nobody has yet explained the transition from the

My point is that if someone is going to claim that the Intensity (taken as watts per unit area) in the near field was proportional to 1/r, then *they* have a lot of explaining to do.

Roy, not quite. The radiation resistance of small loops increases as square of the number of turns in the loop. The resistance increases directly as the number of turns, assuming the same wire size. The overall efficiency can increase as the number of turns as a limit. See Kraus, 2nd ed, page 250 ff. The full increase is seldom realized because of such effects as change in loop area, change in current distribution on th wire, etc. It's one reason Litz wire was used in the old loops. In large loops the radiation resistance doesn't change but the drive resistance does, so the efficiency is essentially
the same.

Hi all,

I was wondering could someone provide me some information about modifying a 5/8th wave CB antenna to have a centre frequency of say 42.5 mhz. I am interested in Low VHF reception and have been having fun in recent times hearing the California Highway patrol in the evenings around these frequencies.

I understand that the length of a 5/8th wave at 42.5 will be 14.47 feet or 4.34 metres. Now I hav'nt opened the butt of the antenna yet but I imagine there is a loading coil in there- how do I adjust this for the new frequency?. How many turns and where do I tap it?.

At present I have the antenna length at 20.5 feet resonant at 30 mhz and it works well from 25- up across 10 metres. It also seems to do quite well between 39 and 43 mhz. Is there any way I can improve bandwidth with such an antenna or should I think of something like a half wave?.

Any ideas or information on this subject would be most welcome- thanks.

regards,

Source record: 147379

Hello everyone reading this, hopefully most of you are either knowledgeable of the goniometer or actually have some input on power line noise removal. I found a great website, dedicated to LF, which I knew might have power line information as them sort of frequencies have much more problems with power line noise than the ones I actually work with. Anyway, the website with information on the device is located here :-
http://lwca.org/library/articles/kh6sr/artndb5.htm

What I want to know is how the phasing works, why does it work etc. I am mathematically minded so plz use equations if you can. I'm currently using LCR ccts in a lab so maybe anologies with such things may help me understand this device better [I study physics]. This goniometer is used in Physics for crystal diffraction techniques I believe, but it has had its Ham Radio uses as well...

'originally developed about 1905 by Bellini and Tosi, that is still in wide use for marine and aero
AD[irection]F[inding] applications.'

For those of you who never knew what a goniometer was, I hope i've brought something of fascination to you, maybe it will have use for you too! It can cancel electrical noises, electrically, rather than moving a large antenna, which is great!

> J. Harvey, in the condescending manner typical of those
> who erroneously think they understand the physical universe,
> <snip>

"physical universe", as in Physics ? Ahem...

I didn't mean to 'sound' condescending. I was just pointing out that theories often work well until someone checks the boundary conditions. And, to be explicit: No, I'm not saying that this silly 'near field' thread is sufficient to render Michael Faraday's field theory invalid (obviously).

The 'theory' in question is the one about 'I=1/r' in the near field (*). The boundary conditions I have previously explained in sufficient detail. That 'theory' seems to fall apart at the seams.

Can anyone step forward to defend this I=1/r in the near field ? Or shall we pronounce it a dead end and move on ?

(*)Assumptions:
-integrated over a complete cycle to avoid the storage red herring
-where I is power per unit area, just like the I=1/r^2 in the far field

==========

The whole lot of you are a set of time-wasting nut-cases, floundering about up to your chins in plots.

It's perfectly obvious how I pronounce "Bode". It is the same as "Boad". I am an Englishman. And these newsgroups are conducted in the English language. The possibilty has never occurred to me there might be any other pronunciation !

I have been designing filters and things, on and off, for nigh on 50 years. I have NEVER used "Bode" in conversation with any other person. No-one has EVER spoken "Bode" to me in the whole of my life. On occasions I have come across "Bode" in text books. When I have read to myself a line of text which has contained "Bode", in order to grasp a point I might have said to myself "Bode", pronounced in my head as "Bode". I never had the slightest of problems on that silly account.

Actually, I never thought very much of him. He's all so obvious. Never used "Bode Plots". Managed very well without him in that respect. But whilst on that line of thought it can safely be said I have NEVER used a "Smith Chart" either.

Now cease squandering hard to come by bandwidth - pleeeeese !

How do you pronounce "Smith" ? "Smythe" ?

Reggie (with hard "G"'s)

While it's a great antenna, I would not be able to put up such an antenna.
I live in a fair sized Mobile home, but the lot is not that long.
I am putting up an end fed long wire on top of the home, but not that high
above the roof.
But, for the time being, it will be for listening only, as it will be a
while before I go for a general license (I am waiting for my tech call sign
right now).
Actually, with a tuner, it is possible to load a random length end fed,
which I did back in the 70's when I had a Novice license.
My biggest problem is that mine will be best for north and south, due to
the direction the lots are laid out here.
Maybe later I can fix up a loaded dipole, but it will have to be under
65'...
A loaded vertical would be easier here.
I'll have to start going to some of the swap meets and see what I can dig
up.
Have to start over with most stuff, being as I moved from W2 land to W6
land...

Wayne K?6??? (waiting is agony)

David, KB5YLG wrote:
"Is there anything more specific...like how many wavelengths?"

There is no rule which says where the near field ends, that I know of, but with the r-f exposure question now front and foremost there probably will be.

The nearest official designation is the collection of "Ground Wave Propagation Curves", which are a part of the FCC rules.. These prescribe field strength measurements starting at 1 mile.

One mile is about 9 wavelengths at the high-frequency end of the AM broadcast band and about 3 wavwelengths at the low-frequency end of the broadcast band.

At the lowest ham frequency, 1 mile is 9.64 wavelengths.

So it`s not surprising that the ARRL Antenna Book would say, "an area bounded by several wavelengths of the antenna".

The far field becomes more devoid of reactive energy the farther from the antenna you are. How much purity do you demand? The FCC only requires about 3 wavelengths.

Having spent years in very intense radio fields and having survived to an old age and knowing others with a similar experience, I think the panic over r-f exposure is unnecessary.

Best regards, Richard Harrison, KB5WZI

Depends on the height of the dipole.
And if you are using open ladder transmission line why would you want
a balun at the antenna feed point?

Reg, I have a vested interest in doing all I can to ensure that *you* among others on this newsgroup never receive a posting from me that contains a virus, worm or other unknown/unwanted visitor.

I paid money for my programs and take extra time with each posting to allow the program to do its thing.

Should I do less? No . . .

Do I wish that everyone did the same? Yes . . .

Source record: 147437
Cross-posted to: rec.radio.amateur.antenna,alt.engineering.electrical,sci.electronics.design,sci.electronics.basics

Reg:

Bode plots have perpetuated his name, Bode plot techniques are a devilishly simple set of rules for plotting frequency responses developed in the age before computers, but that certainly was not Bode's major contribution to modern electronics Engineering.

There's a whole lot more to Bode than Bode plots...

If you can beg or borrow a copy of H. W. Bode's famous treatise "Network Analysis and Feedback Amplifier Design", Van Nostrand, New York, 1945, I am sure that you would appreciate his elucidation of network analysis, synthesis, and feedback amplifier theory. That book is just chock full of insights into the analysis, synthesis and operation of electrical networks and active impedances. Bode was among the first to point out the nature and details of the relationships between parts of network functions, and how the introduction of gain and feedback affects them. And so his work led to the idea of active filters, operational amplifiers and such. Between them Hendrik W. Bode and Harold S. Black "wrote the book" on feedback amplifier design.

Unfortunately, or perhaps fortunately, Bode was a very skillful mathematician. Because of this many of his presentations demand quite a high level of mathematical sophistication on the part of readers. Many say that his book is "too hard". That mathematical sophistication is probably the reason why he is not so widely read as others. However if you read his stuff, and note the dates, you will see that he was "a leader" and most others just followed him later.

Sort of like James Clerk Maxwell, Claude E. Shannon, Norbert Weiner, Oliver Heaviside and others of that ilk. i.e. prescient and somewhat before their time.

You got it man! If a business person wants me to buy their products, I have th see what they are selling.

A large part of the problem is that business people often don't know much about the web, and cyber-geek designers tell them if they want to have a proper web presence, they have to have Flash animations, and browser specific crap that in reality has nothing to do with what they are selling.

When Flash was just starting, I went to a web page looking for skates. The page wouldn't load. Told me I had to download Flash. I did. I had to disconnect from the web, install, and reboot. Then it froze my computer. I rebooted and went back to the page. By this time I had decided that I wasn't going to be a customer, but I wanted to see what was so all fired important that Had to be presented in a Flash animation.

It was a short clip of a goalie sliding in front of a net. Of no real content whatsoever.

If I can't see it, I can't buy it.

Oops, sorry for the rant. 8^)

Because, man - if you aren't on at *least* a DSL, you are just not worth
it! - Just Kidding!!

But I think some people really think this way.

Aside from what some people think, I wonder what the person who owns the
business thinks about the sizable number of people who won't buy from
them because they can't see their website?

Hi Piero,

I was thinking more about the group of experimenters and gurus on this
side of the pond myself......

I built a simple one from tin foil and a cardboard mailing tube, but
without a dipole antenna to compare it with.................

But then again, if I could put up a proper dipole I wouldn't need a
compact antenna, right?

I wonder what the logic is that would prompt a business to purposely exclude so many customers.

With the dot.com world so shaken up it is surprising they would do this.

Kind of like gas stations refusing to sell premium gas. I mean really, there aren't that many people who use unleaded right?

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C82DE79.DF2E6952@eznec.com>
Source record: 147444

The characteristics of the balun -- or choke -- are determined entirely by the outside of the shield, not what's inside the coax. So the characteristic impedance of the cable has nothing to do with how the choke works.

Nah, that's not a real rhyme, (even though I at first pronounced
it "bow-dee," which I haven't heard anyone else report), because
the consonant in the final syllable is different. ;-)

marvin,
If the coax is 50 ohms, and the antenna input impedance
is about 75 ohms, you only have an SWR of about 1.5:1. No
big deal at all. So if you just have to use a balun, why
not use a 1:1 balun?
'Doc

4368. Stacking Dipoles?

Newsgroup: rec.radio.amateur.antenna

'ö'....

In most book I have read, in several languages, is has been
written as ö, but you are maybe right in that it in hungarian is
written differently.
The hungarian letters are probably not commonly available in
typesetting of books in other languages. But I have seen it
written with a more strange umlaut too, that was probably the
letter you are talking about.

I think it is pronounced like ö anyway.

> >ö is pronounced like the first wovel
>
> Pardon?

Pardon what?
Never mind, you can probably understand that sentence from the
context if you think again. (There is an awful lot of newsgroups
involved here, I will not reply again unless really necessary)

> > in these english words:
> >first, sir, purly, colonel, heard, girl, curling..

and "herd"

so the sound ö can be spelled with i, u, o, ea, e.. in english.

Roger

Dick,
Since you already have what sounds like a fairly
good 'ground', pick a vertical antenna that you like
the looks of, and have at it. There really isn't
~that~ much difference between most of the commercial
verticals (except price). Putting it on your roof
will get you a few mile miles to the horizon, but also
will mean putting up some counterpoise(s), take your
pick.
Cecil won't like it, but if you have a good tuner,
it would probably 'smooth' things out if you can't get
everything tuned exactly as you want it. As far as the
balun goes, a vertical isn't a 'balanced' antenna, why
bother?
'Doc

You may want to rethink that statement. The choke affects the current flowing on the outside of the coil. It does nothing for the current inside the coax. That means that you add the equivilent of however many feet of 75 ohm coax you use for the choke to the transmission line. It will have the same effect as adding a stright piece of 75 ohm line and then putting some ferrite beads on the outside of the 75 ohm line.

Hi J,
Good observations about the energy on the surface of a sphere.

As far as I remember, no one yet has explained where the 1/r fall-off
in the near field has come from, but it keeps getting repeated like
it's fact. Maybe someone should post a reference so we can all read up

on it.

Let me try to expand on an answer to another post. Suppose that the power density is measured in the far-field region of an aperture antenna. As distance from the antenna decreases, but still in the far-field, the power density increases according to 1/r^2. I think everybody agrees on this. At some point, the PD does not increase as 1/r^2, but at a slightly smaller value. This makes sense since the PD can't continue to increase because it would become infinite.

There are 2 basic descriptions of what happens in the near field of an aperture, depending on the aperture shape. The basis for this is (as I recall) an IEEE paper by Hansen. I'll see if I can dig up a reference tomorrow in case people would like to track it down. From here on out, I'm going on memory, so bear with me.

For a rectangular aperture (with uniform distribution?), the near-field PD oscillates as the distance decreases. However, the envelope of the oscillations remains relatively constant with distance. A conservative answer is to use the envelope value to get the near-field PD. If more accuracy is needed, an effective near-field gain is obtained from the far-field gain by applying near-field correction factors. So for most of the near-field region, the (envelope) PD is constant, not 1/r. What happens when the distance from the aperture is extremely small is something I've never had to be concerned about, so I don't know what the variation is. There's probably a reactive field that has some other variation.

For a circular aperture (also with uniform distribution?), the PD also oscillates as the distance decreases, but the PD peaks at a certain distance from the aperture. The envelope PD decreases as the distance decreases (not increases as 1/r). I don't recall what the falloff rate would be.

The transition from near-field to far-field occurs because the beam is not fully formed in the near-field region. The oscillations are due to contributions from different parts of the aperture adding and then cancelling. This can be demonstrated using a simple flashlight.

I found the theory for the near-field from a short dipole in Kraus's Electromagnetics, p. 612 (2nd edition). The E-field is the sum of 3 terms, one in 1/r, one in 1/r^2, & one in 1/r^3; the H-field is the sum of 2 terms, one in 1/r and one in 1/r^2. Since E-field and H-field are both sums, neither of them fall off at 1/r. Power density would vary according to the cross product of these two quantities, but there's no way this product is going to be 1/r.

The transition for the dipole occurs when the E-field component in 1/r^2 equals the E-field component in 1/r. At larger distances, the component in 1/r^2 falls off much faster than the E-field component in 1/r and becomes negligible.

I agree - this whole I=1/r near-field thing is a mess. 73,
Bill N3WK

The CC&R problem is bad. We're not just talking about ham radio here, but lots of things prohibited by these silly exercises in suburban conformance. The problem is that the folks making the Covenants and Restrictions often don't understand and don't care about the social consequences of what they're doing.

They're thinking that we should all live perfect lives in Duloc (as in the movie "Shrek") and by doing this they'll keep property values high. Only time will tell if they are successful. I have a stinking suspicion that some day urban blight will visit their neighborhoods too.

We can't all be big guns. One of the main features of this hobby is not to see how reliable we can be, but how little we can get away with.

Bode's name is Germanic, and pronounced Bo-duh (with the "a" having very little emphasis, and sounding rather like the sound of the "u" at the start of "under").

This is the same as the proper way to pronounce "Porsche" (no, it does NOT rhyme with "porch", you infadels!! :)). German may be a pain to learn because of its complex grammar, but at least (unlike English) it obeys its own rules for pronounciation. The "e" on the end of any Germanic word is always sounded.

Bob.

Just because you are an Englishman, doesn't mean that you have to go around mispronouncing people's names. Fact is that the english language (in spite of its vastly simplified grammar compared to other languages) is a bloody disaster when it comes to consistency of pronounciation. Show the guy some respect and don't use English language rules (as sloppy as they are) to pronounce names that are rooted in other languages.

An ancient synapse fired while reading this post. At about the same age,
(and back in the days of B&W TV), I got bored with my electric train.
It had a transformer that took in 120 V and put out between 0 to 12 (?)
for the track. I also had a Morse code practice buzzer. Having read
some books on the history of radio, and a smattering of electrical stuff,
I wired the CPO buzzer to the low voltage side of the train transformer
and attached the 120V plug to the clothes line. I can't remember how
much of the AM band was smeared with noise, but the experiment ended
before any charges were laid.

Many of the common "viruses" (technically, worms) being sent today -- including the one Reg's machine was recently infected with -- are being sent via paths that completely bypass programs like Norton Anti-Virus. NAV checks only the outgoing email that you intentionally send, and downloads from web sites. The common worms send email messages without using the browser, and without your knowledge -- and without NAV's knowledge. And your system can contract them from places other than the email and web sites that NAV monitors. If you don't have a firewall, a hacker could get into your system and implant a worm without you or your anti-virus program being the wiser. That worm can then send infected emails to others without using your browser, again without the anti-virus program knowing about it. There are a lot of firewalls available, and installing one will go a long way in preventing a worm or other pernicious software from being installed on your machine. Zone Alarm is one of the very few that will also spot outgoing messages being sent by a worm, should one ever get onto your machine. But Norton Anti-Virus doesn't prevent a worm from being planted by a hacker, or notify you when the worm sends infected email to others.

I can't restrain myself.

Two semi-retired professors were sitting on the porch having a couple
of brewskis. (This could also be referred to as a "verandah" or "deck")
- it was a fairly sizeable porch, encompassing three sides of the house,
and as it happened, it was badly in need of a paint job. The two old
fellows were discussing what a pain in the neck it would be to paint
it themselves, and how expensive it would be to hire pros, when
suddenly a young blonde shows up. "Hi! I'm LuAnne, and I'm working
my way through college! Got any work for me?" Well, this is too good
to be true. The professor says, "I'll give you fifty bucks to paint
my porch." She says "Sounds great!" He says, "Well, all the paint
and brushes and stuff are over by the garage back there." This is
fantastic! He's just saved over a thousand dollars! And made a
young bimbo happy! But after about an hour or two, they notice
that she hasn't come around the corner painting the porch, so
they (the professor and his friend) start to get a little concerned.
While they're discussing this, LuAnne shows up, paint-stained,
with a little bead of sweat at her temple, saying, "All Done!
And I had so much paint left over I gave it two coats!" The two
old guys look at each other, wondering, "What the F?" And LuAnne
says, "But, you made a mistake. It's not a porch, it's a Ferrari."

Many dipoles do use a balun instead of a ladder line.
And, contrary to what some might tell you, it is possible to use 50 ohm coax direct to a dipole.
I did so in the past with an item called a trick stick, which was a half wave dipole usable for 10 meters, and even 6 IIRC.
It could be put up horizontal or vertical, and came up with a quite acceptable SWR reading using only some RG8 coax.

Would they be related to the two Indian chaps on a bus in Bradford?
They were discussing spelling. One said "It is Woom, spelled W O O M".
"No, no", said the other. It is "Woomp - W O O M P".
At this point the Englishman in the seat behind leaned forward and
said, "Excuse me for interrupting, but it is actually Womb, spelled "W
O M B".
One of the Indians turned round to him and said, "Sir, I doubt whether
you have even seen an elephant, let alone heard one fart".

Such a vowel as ö when in a non-tensioned position loose a lot of its special character and the name Erdös might well be heard and written by an american as Air-dish if you do not stress the i-sound (ee) in dish either. So I understand how this confusion has come up.
It could just as well be written phonetically as Air-dsh, but that would confuse some people when there is no vowel at all there.

I am pretty sure though that when stressed the ö in hungarian is very much like the ö sound in other languages, otherwise it would not be translated with ö.

Yes it is possible with both antenna`s on a full wave length from each other (vertical?) ! You will get 3 dB gain. You need to use 75 ohm coax and the length of that coax must be 3/4 wave lengt to each site. Connect your feedline in the middele and you are on!

Correct me if I am wrong!

Hi Stefano,

In fact you have failed to demonstrate any claims to anyone here.

This could only arise from one of several conditions:
1. you cannot yourself build an eh antenna;
II. you cannot yourself tune an eh antenna;
or, more likely;
c. your claims are false.

Isn't there a better spokesman among your group that could present us
evidence that they could
A. build an eh antenna;
2. tune an eh antenna;
iiv. present unbiased data that show your claims are valid?

There's one example off the top of my head, and I think there's
another, but can't think of it, but anyway, Pierre, SD is pronounced
"Peer," not "Pee-air." Of course, there's the eternal argument between
"Saint Loo-iss" and "Saint Loo-ee," and god knows how many possible
pronunciations of "New Orleans." Anybody recall that other famous
example?

> shack.

The impedance is only 50-75 ohms on the design frequency. "1/2 wave".
In that case,only a 1:1 balun is needed. If you use the antenna on
other bands with coax,balun,and tuner, the losses will be high on most
other bands. IE: If you use an 80m dipole on 40m, the impedance will
be very high. Even with a 6:1 balun the losses will be high using
coax. MK

Anyone who has any training in navigation, such as pilots, knows this.
As I recall, in the Los Angeles area it would be at least 60 degrees
off!

Another good source is Aviation Sectional Charts put out by the FAA.
Don't remember what they are called in Canada.

I learned a memory aid when getting my pilots license: "East is
Least, West is Best. Rule is True when you start from True".

Mathematically this can be stated: Magnetic Bearing = True Bearing -
Easterly Deviation, or Magnetic Bearing = True Bearing + Westerly
Deviation.

I leave it as an excercies for the reader as to how to apply this to
aiming an antenna.

What is it you are trying to accomplish? There are a number of ways to combine the antennas- and yes, you can achieve some gain- but it will be dorectional, so w/o the means to rotate it, you will lose in other directions. It would probably be easier to put up the 2nd wire as a reflector or director- w/ proper spacing you can maintain 50 Ohms, get directionality and have to feed just the one element.
re: the harness- the lenght must be adjusted to take into account the V.F. of the coax you decide to use.

>notify you when the worm sends infected email to others.

>Roy Lewallen, W7EL

Even on OS/2 I use a hardware firewall as well as a software firewall
for better log and trace advantage .. plus checking software, just to do
as good a job as I can from even passing anything on through the system
or the number of BBS operations the site hosts as well.

For any of you that use OS/2 you should also be careful how you
implement NETBIOS over TCP/IP as a protocol! Although OS/2 makes you
decide exactly what and how you do everything on install, rather than
assuming you want it, there are some otherwise ought to be gotcha's that
have vectors to you with that one. On installation of OS/2 even as PEER
LAN applications with no formal server .. please change your ADMIN name
and password from the vanilla install one. As well, the vanilla install
leaves the GUEST user as one with no password!

The disadvantages of running OS/2 even with no hardware NAT and firewall
and a software firewall alone can be seen with the following.

NETBIOS over TCP/IP was deliberately designed with the idea that a
standardized communications interchange can be made between computers
which have vastly different operating systems! It was the intent! Yet
. lookee here!

An example of oblique entry with NETBIOS over TCP/IP here with OS/2 is
the MIRANDA.A W32 virus which can use Port 137/138 and thence Port 139
to compromise a box on a one in xty-xty chance that a corruption in it
will think that it was successful at creating a new GUEST with ADMIN
priviledges when in reality, GUEST with no password is already on the
box! As one of the very few pest vectors, that can actually let this
one begin to download tons of files to that box which fill the thing up
with at least one in every directory and subdirectory in the found hard
drive partition!

No, they won't execute under native OS/2! And no, JAVA in OS/2 is still restricted to better confinement in the sandbox! But, they are still there! They have to be cleaned out which takes time and the tools such as NORMAN offer (Not NORTON for OS/2! It exists, but it is hard and expensive to come by!)

It is darned well possible to write viruses for OS/2, just seems to be not 'productive' enough for those with the ability to do so and much harder in many ways.

So as Roy so aptly put it .. do what he says. There is almost no way in this world of modern connectivity to minimize your risk without that approach and it is a VERY real risk. That, even if all you do is have your system pass down junk to everyone else, which .. at least in WIN32, something like ZONEALARM will help you to see.

It will get a lot worse. Ever considered how our ham techniques like spread spectrum RF hopping could be adapted to site hopping using the entire internet as the "spectrum"? (!)

It isn't so important that you have a scarlet letter "A" on your forehead, folks. It is how you got it that counts....

--> Sleep well; OS/2's still awake! ;)

<snip>
>
> And nobody has yet explained the transition from the far field (I=1/r^2)
to
> the near field (I=1/r). It obviously doesn't "shift gears"
instantaneously.
>

My 2 cents worth::

In the far-field, the EM field components, E and H, decline as a function of 1/r. The power contained in the EM wave, which is a function of E x H*, declines as a function of 1/r^2. In the near field, the E and H fields decline as a function of 1/r, 1/r^2 and 1/r^3. Energy decline in the near field occurs at a rate much quicker than 1/r.

The conventions or definitions of near-field and far-field are primarily based on the mathematical study of the E- and H-field components of small antennas, the infinitesimal dipole and loop being prime examples.

In discussing the EM field components, it is important to recognize that an electromagnetic wave is described by the amplitude, phase AND polarization of both the electric field and the magnetic field. The boundaries between the near and far-fields are not instantaneous. They are simply defined as a function of which field components are dominant as a function of distance, r, away from the antenna. They can also be defined as a function of whether or not time average power flow occurs in the radial direction.

In the far field, where kr >> 1 (k = 2 pi/lambda), the dominant E- and H-fields will primarily be a function of 1/r. For a dipole antenna, the dominant E-field polarization is E-theta (parallel to the dipole) and the dominant H-field polarization is H-phi (perpendicular to the dipole). In the far-field, the dominant E- and H-fields will be orthogonal to one another and orthogonal to the direction of energy propagation.

In general, there are three field components associated with the electric and magnetic fields. These are defined using the spherical coordinate system. These field components are defined as E-theta and H-theta, E-phi and H-phi, and finally, E-radial and H-radial. For the infinitesimal dipole, the electric field has a radial component and a theta component. E-phi = 0. The magnetic field has a phi component. H-theta and H-radial = 0.

E-radial is a function of 1/r^2 and 1/r^3. E-theta is a function of 1/r, 1/r^2 and 1/r^3. The near field and far field boundaries are a function of which terms (1/r, 1/r^2 and 1/r^3) are dominant as a function of distance r from the antenna.

In the reactive near field, (kr << 1), both the E-radial and E-theta fields are primarily defined by the term 1/r^3. E-theta and E-phi are in time phase but they are in phase quadrature with the H-field so there is no time average power flow.

In the intermediate near field (kr > 1), E-radial is primarily defined by the term 1/r^2 and E-theta is primarily defined by the term 1/r. In this region, E-theta and H-phi begin to approach time phase and radial radiation begins. However, E-radial still exists. The radiation patterns of the antenna will differ as a function of distance from the antenna.

In the far-field (kr >> 1), E-radial goes to zero and E-theta is dominant and a function of 1/r. E-theta and H-phi are in time phase and radial power flow occurs. The radiation patterns no longer vary as a function of distance.

For most practical antennas, the field regions are separated into three regions - the reactive near field, the radiating near field and the far field. The boundaries of these regions are approximated as a function of the antenna size. The reactive near field exists (approximately) from r = 0 to r = 0.62 Sqrt(D^3/lambda). D is the maximum dimension of the antenna. The radiating near field exists between r = 0.62 Sqrt(D^3/lambda) and r = 2 D^2/lambda. The far-field exists beyond 2 D^2/lambda.

My 2 cents worth::

In the far-field, the EM field components, E and H, decline as a function of 1/r. The power contained in the EM wave, which is a function of E x H*, declines as a function of 1/r^2. In the near field, the E and H fields decline as a function of 1/r, 1/r^2 and 1/r^3. Energy decline in the near field occurs at a rate much quicker than 1/r.

The conventions or definitions of near-field and far-field are primarily based on the mathematical study of the E- and H-field components of small antennas, the infinitesimal dipole and loop being prime examples.

In discussing the EM field components, it is important to recognize that an electromagnetic wave is described by the amplitude, phase AND polarization of both the electric field and the magnetic field. The boundaries between the near and far-fields are not instantaneous. They are simply defined as a function of which field components are dominant as a function of distance, r, away from the antenna. They can also be defined as a function of whether or not time average power flow occurs in the radial direction.

In the far field, where kr >> 1 (k = 2 pi/lambda), the dominant E- and H-fields will primarily be a function of 1/r. For a dipole antenna, the dominant E-field polarization is E-theta (parallel to the dipole) and the dominant H-field polarization is H-phi (perpendicular to the dipole). Second that! For some yet unknown reason (water in cap's, arcing coax,
???) the SWR on the XYL's Butternut skyrocketed and smoked the tubes in
her amp just before the contest this past weekend. So I jury-rigged an
inverted V using two of the Butternut's 40M radials and she worked
something like 150 (IIRC) stations worldwide on 20M and < 100W in two
4-hour sessions. Must prove sumpin .. ;o)

Don't feel too bad about that. Most people guess that my name is pronounced with two syllables: pope' lish, but my family uses 3 syllables: poe pel' lish. In grade school, my nick name was propeller because people who heard it sometimes wanted to repeat it with an r in it.

I think the immigration people screwed the spelling up when my grandfather arrived in the US, but he brought the pronunciation with him. It may have been better to have spelled it ending in ch. My daughter just discovered a very similar word being used as a label for a religious heretic group in the dark ages called the Cathars or Popelicants. Perhaps it is connected to them.

Math is not my fortï¿½, but this is a very simple concept. And no, I
don't know what a goniometer is.

If you have two signals of equal amplitude, and opposite phase, they
will cancel, making them both disappear. To cancel noise, be it AF or
RF, what is needed is a device that allows you to feed the unwanted
signal back into the receiving device (radio receiver, your ear, an
amplifier, whatever) and control its amplitude and phase so that it
exactly cancels the original signal.

Expensive cars are now doing this to lower noise levels. They use
microphones to pick up noise that you would hear as you are driving down
the road, amplify and control them so that they feed speakers inside the
vehicle with a canceling signal, making the vehicle much quieter.

If this isn't what you were asking, I apologize and will step aside.
That's the way I understood the question.

My favorite 2M antenna is a 5/8 wave with a coil to match it to 50 Ohm coax. Works so good I've been considering a "fixed" equivalent - kind of like a Texas Bugcatcher; eg, a 33' vertical with a coil between the bottom and ground using "Roach Clips" on the coax feed to select appropriate feed points for each band. If you try it lemme know how it works.

WHOA! Don't confuse the poor guy even more with misinformation!
Someone that ignorant of a subject needs proper information, not
something that is totally wrong. LA is on a line somewhere around 14
degrees off of true. I don't have a proper area map, but SFO is about
15.5 degrees, and Fresno is 15 even.

To be proper, the magnetic pole is constantly moving, so these may be
off be a degree or so, as they come from old charts. Either way,
knowing your area's generally accepted error is enough for any antenna
pointing over a lifetime.

If there's enough interest in this subject, I'll see if I can dig up a
url for better explanation. I know there's one somewhere on
http://joe.mehaffey.com/, the biggest single source of GPS and
navigational information I know of.

Okay Mr Harvey. At the moment i forgot about the dish, since its for professionals...

Now, here is what i came up with for a better reception. You have to tell me.. if i am wrong.

I went to RadioShack the other day and saw a SW antenna kit, for 10 bucks. I guess its one of those 'Inverted L' kinda of antenna.

Now i plan to install that antenna in the backyard, and then buy a MFJ Antenna preselector. As i saw some articles in the net saying that will be a powerful combination.

My problem here is... the connectors from the Preselector, are co-axial..or whatever to the radio.

But my portable has.. a MINI Plug for..."Ext Ant".

How do i connect that output from the preselector to my radio.

Secondly.. apart from lightning and static.. will it damage the sensitivity of my Sony Portable in anyway !

Reply and your valuable advice is appreciated..since am pouring through.."passport to world band radio" and "ARRL Handbook" at the moment..to get a decent SW reception here.

I cant sit by my window with my telescopin antenna,, since its cold and the windows are always closed. And i am not really satisfied with the supplied reel antenna.

And according to reviews.. the SONY AN--LP1 seems to be the best antenna there is.. for a portable, but not available in the USA at the moment.

So... what say you... Mr.Harvey ?

4421. help on NMT 900 systems

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-04 15:49:46 UTC
From: Jean-Michel Rouquette <elfjmr@elmagn.chalmers.se>
Message-ID: <3C83979A.61803EAA@elmagn.chalmers.se>
Source record: 147408

hi everybody,
For research purpose we would like to use a "old" NMT 900 Base Station
BS901
as a generator to produce a powerful microwave signal.
I have the technical documentation and the user manual, but in local
mode
it´s impossible (i didn´t succeed) to simulate a handshake with a mobil
phone so I cannot have an output signal (should be FM 900MHz 30Watts).
In the normal configuration this BS communicate with an MTX across RS485
interface, it seems that the MTx have full control of the BS.
so i think that i must simulate a mtx with a computer but i do not have
the
software manual of the system so my questions are:
1 do someone know about the system BS901 (or equivalent)
2 do someone know if it´s possible to run the system in local mode (not
for
test pupose!)
3 do someone have the software manual of the BS 901

Other thing if you live in Sweden or close,
for approximately the same purpose I look for a booster working at these
frequencies (~900MHz) used before during the NMT generation in car for
external antenna:
i need 7Watts output for 2 watts input so if you have such a thing
please
make me an offer feel free to mail me or phone 031 772 1723 (sweden)
I will be very pleased
Thanks for your attention

Have you looked into the 'Phifer Quad'. He published an update in QST
(issue?) in 2001. Search ARRL or Google for the info.
A bit more mechanically complex but fits a 40 meter quad within same space
as 20 meter loop! (20 meters in 10 meter space, etc.) The loop is
continuous but looks like a large cross. If you can't find the info, I will
look for the local file I have.

Richard Clark has a copy of Arnold B. Bailey`s "TV and Other Receiving Antennas", I believe. He can confirm my interpretation of the "Free-space power graph showing near and far fields" on page 211.

In the near field, the signal drops about 11 db when the distance is increased by a factor of 10. In the far field, the signal drops by 20 db when the distance is increased by a factor of 10. This just a graph on a small scale constructed by humans, but it agrees very closely with the assertion made by Chip.

Best regards, Richard Harrison, KB5WZI

4426. UHF Antenna selection

Hi all,
I know this is probably off-topic, but I need help. I need a UHF ant to pick up local TV. Roof-top mounting is out due to neighborhood restrictions, and attic trusses limit me to an 86" boom lenght if I want to rotate. Channelmaster has an 8 bay bow-tie they claim is good for 60 miles. Winegard sells a similer type. I've always had corner reflector UHF antennas, but the bow-tie would be easier to mount in my attic. Any testimonials as to which way to go with this would be greatly appreciated.
Thank you, Sam

"Naw-lins" is the way natives (even the Cajuns) pronounce New Orleans.

When I lived there, it took me a long time to get used to articulating
Miami, FL as "My-ama" as the natives do.

Baton Rouge (red stick)?

(the red stick in question is a result of a kind of red fungus that grows
in the American south. You can find it in Florida too.)

The UK has lots of places that the natives pronounce strangely in order to
more easily identify outsiders- Reading (redding) and Leister (lester),
for example. What do you expect from a people who pronounce "Infanta
de Castile" as "Elephant and Castle"?

(yes, I know it's disputed, and probably untrue, but it's a good story).

Could you listen to any station? Did some station listen to you? With which
signal, power and QRB?

> But then again, if I could put up a proper dipole I wouldn't need a
> compact antenna, right?

Right! The famous DX and contesting stations, that I can only see on a
picture :-(, really don't need EH at all.
But here we are discussing about the fact that this new 'object' works,
works well, doesn't work at all, just to satisfy our technical 'need to
know'. Moreover, if I could replace my 160mt dipole, that lies almost on the
ground, with something more efficent, it would be great.
Hope to hear you on the air, in the top band....by mean of ...any antenna!

Hi Richard:

I don't have the book you speak of so I can't comment on how the near field number of 11 dB was determined. I wonder about increasing the distance by a factor of 10 and still being in the near field. In any event, I may very well find myseld standing corrected on my initial comment in the post regarding the rate of radial power flow decline in the near-field. I'll think about it a bit.

I'm not sure I understand. A perfect 6:1 balun would take 72 ohms down to
12 ohms causing an SWR of 4:1 on the coax. Is that what you really want?
The reason for using ladder-line is that it tolerates a relatively high
SWR with relatively low losses. The coax needs to be minimized, not
maximized.

Hi Richard,

After having spent some ten or more years in the study of light
radiation consisting of several complex components, the graph you
reference exhibits those same relationships.

That is, there are three distinct phases exhibited in the graphics
offered. There is the peak of the curve closest to the antenna with a
very small slope, there is its roll-off which is a fairly even
mannered high slope out to the 3rd wavelength, and then there is the
dominant, modest slope of the curve, log-linear from 10 wavelengths
out to 10,000 (and presumably well beyond). Thus there is an odd
region that exists between the 3rd and 10th wavelength where the slope
reverses its decline.

All of this is entirely consistent with Steve's unacknowledged
correspondence in this side thread.

I've read of how fields are imaginative devices (where I have to
suppress the urge to point out that Physics long ago reduced ALL
matter to fields - and we are thus offered the conundrum of living in
a fantasy); I've read that the 1/r law is unsustainable at the
boundary conditions (which is the whole point of such provisos); and
I've seen the most obvious boundary condition missed entirely.

To this last point, the unexpressed boundary condition. As inferred above, I tend to "see" radiation in terms of light (which is, after all, the genesis of the topic) and antennas as lenses. For some reason, many have the common experience of these two related topics and yet cannot bridge the discussion for themselves. The single most obvious boundary condition is found in the relationship of wavelength to distance from the radiator. From a distance, you can make measurements that are consistent over a great range (and this is manifest in the >10 wavelength slope); however, as you approach the emitter, it ceases to be a point source. This is the first and most pernicious unstated presumption of all the math being tossed around. That is, for the math to work, the source and the detector must be point equivalents in that same field.

We do not use instrumentation that qualifies in that regard, so measurement itself must contribute to the perceived error. However, this is not a fault, strictly, of measurement. Rather it is an error of the measurer's faulty conclusion that such a test was valid. That is, the failure of 1/r as an example is found at the boundary of r -> 0 (r approaching 0). It is more than obvious that a radiator at that distance cannot employ the math of point sources to forecast measurements made by gross instrumentation. The graphs offered for any of this discussion (including Richard's and my favorite author, Arnold Bailey) do not show a solution at 0 through the simple imposition of the semi-log format of illustration. The graph offered simply starts at 1/10th wavelength (there being no reason to intuit any "gain" in radiation as r -> 0, provided you do not go beyond the boundaries). In fact, the curve appears to be asymptotic below the 0dB reference point (which allows for the argument to be able to sustain a complete integration of the source radiation without breaking the power budget).

Now, as to the angst over where the 1/r, the 1/rï¿½, and the 1/rï¿½ slopes depart from one another. Too much is put into the associations without regard to their whole indifference to one another. The three processes are tightly bound, but are not in themselves separably significant EXCEPT at a very close distance. There, where they may be appreciated, you have to leave behind the math that got you there. For my own pursuits in research for the NIH, I had to worry about such things as I was forced to make measurements close to the non-linearities. I knew what the sources of the different slopes were, but knowing them did not allow me to extract any particular slope, except mathematically. In other words, the three slopes were inseparable in both their Physics and their physical manifestation. However, knowing the sources of the three slopes and their values allowed me to fix a point out along the "far field" line where I could mathematically prove that the other slopes could not contribute a significant amount of error to that same point. This, too, presents an artificial distinction (the fields inter-relate in no different fashion before or after this point) that is meaningful only for my research. With this anchor as a reference, I could then cross-correlate back closer to the peak of the curve as I changed

conditions (but not the boundaries). In other words, I had to originate the math appropriate to the "near field" condition through extrapolation by observing the boundary conditions in the "far field" condition.

To put numbers to this juggling game I pursued; I went from an accuracy of ï¿½20% in slope determination to ï¿½0.05% well inside the boundaries that would have otherwise confined me to that abysmal first pass rough reading. As I said above, such a gain in accuracy did not come by virtue of academic niceties that could never be realized in a physical world; they arose of ad-hoc, but adequate methods that observed the boundaries AND the premises.

The AEA CIA-HF is the best I have used:
http://www.aea-wireless.com/via.htm

I have an older Autek RF-1 that no longer gets used. CIA is
superior on all fronts except size & cost. The cost is
justified if you use it a lot and within your budget. Also
used MFJ-259Bs a few times - not in same class as the AEA.

Also, check the eham product reviews at:
http://www.eham.net/reviews/products/31

>Tom Donaly KA6RUH

Hi Tom,

You missed one fine point of Cecil's definition that was extracted
from the IEEE (and I am not sure Cecil caught it either).

The dipole mentioned was specifically called an "Electric Dipole" (or
rather the radiation's projected shape). This did not mean an open
ended (as distinct from a close ended or loop) antenna. It means that
the form of radiation conforms to the field lines presented by two
point charges separated in space which constitute this same "Electric
Dipole." The two point charges are equal in magnitude but opposite in
charge and are thus balanced in more ways than one. Their graphical

field lines and those of the common dipole antenna presented in academic texts are indistinguishable from one another.

There are other forms of dipoles. Water, as a molecule, is electrically dipolar, but its physical form is not (and it is dipolar because of this imbalance). When we reduce the word dipole to these many meanings, two poles, we can all agree that context is necessary.

Source record: 147287

I was reiterating a previous set of comments I posted on Arnold B. Bailey`s near field / far field observations by reporting what was on one of his graphs.

I had already reported that Bailey said the near field is the complex summation of three fields. The electric vector (related to the voltage) decays as the cube of the distance. The induction field decays as the square of the distance. Finally, the radiation field decays linearly as the distance grows.

These fields which make up the near field are not in phase with each other, and we have the combination of these constituents which are declining at different rates, making a messy problem in their summation.

Bailey has worked out the solution and graphed it for us. In the near field the slope of decline is changing as opposed to the far field which has the well-known slope. So, the bottom line is that the near field slope is not as precipitous as the far field slope is.

I wasn`t taking aim at anything anyone said. I said again that Chip`s comments on far field / near field looked substantially correct to me.

Best regards, Richard Harrison, KB5WZI

Hi Richard:

As I thought about this further regarding the statement in my first paragraph and your comments above, I am not sure that there is really a simple answer to the rate of energy decline in the near-field. I would however correct my first paragraph slightly to be consistent with the remainder of my discussion.

In the far-field, the magnitude of the propagating E and H-fields declines at a rate of 1/r, while the energy associated with them declines at a rate of 1/r^2. I think we are all in agreement on this.

In the near-fields, the magnitude of the E- and H-fields (the components that define far-field propagation) decline at a different rate, sometimes consistent with 1/r^2 or 1/r^3 (this being a function of distance VERY close to the antenna). Associating a propagating energy or rate of energy decline with these near fields is a more complex issue.

In the reactive near field, there is no time average power flow, so the rate of propagating energy decline as a function of radial distance has no meaning.

The radiating near-field is a transitional region, where the propagating fields begin to become dominant but there may still be a component of radial field and the patterns will vary as a function of distance. The most important issues affecting our assumptions and discussion in this field

region is the size of the antenna and the operating wavelength. For very small antennas, the radiating near field is sometimes non-existent. For antennas in the 0.5 to 1.0 wavelength size, this region will begin near the antenna and extend out to maybe 2+ wavelengths. For antennas of this size, discussing the rate of energy decline in the near field when increasing the distance by a factor of 10 is for the most part meaningless because the radiating near field may not have that great an extent. For moderately large antennas, the radiating near field may begin several wavelengths away from the antenna but still may not extend out to 10 times that distance. For very large antennas, the radiating near field region will begin further away from the antenna and may extend out a distance 10 times the inner bound. However, I think that at the outer boundary of this radiating near field, the properties of the EM wave will mostly match those of the far-field. Near the inner boundary, I question the validity of trying to define a "rate of near field energy decline" out to several tens of wavelengths of distance. I would expect this rate to vary somewhat over the full extent of what we might define as the radiating near field zone. (note that the numbers used here as examples will vary as a function of both antenna size AND operating frequency)

I would still like to see the reference for where the near-field energy is presumed to decline at a rate of 1/r. It does not seem to be in my reference library of antenna texts.

> it. How long is the 75 ohm matching stub?
>
> Jeff Y.

Jeff, look here http://www.bencher.com/pdf_download.html for all the info you could want on Butternut verticals.

The matching line for 20m impedance transformation is 13ft 6in for 0.81vf co-ax, or 11ft 4in if the vf is 0.66 ie: RG59. This matching line must be 75 ohm feeder. It has no effect on any other band, or the efficiency of the antenna at all, it simply transforms the 100 ohm feedpoint impedance on 20m to 50 ohms so that you do not have a permanent 2:1 SWR on 20m.

Hope this helps.

George, W5YR wrote:
"How does one "turn off" an antenna?"

That`s a question a broadcaster must answer when a resonant structure is erected close to his station. The structure must be detuned so as not to accept significant signal, which would screw up the radiation pattern and inervate the radiation.

A structure that`s ungrounded and near 1/2-wavelength or a grounded structure which is near 1/4-wavelength could be trouble.

Actually, it's 135.975, 720 channels total.

>>The middle of the band is 121.5 mhz (also the emergency
>> frequency 121.5

>No, sir, the middle of the band is (sqrt ((118^2 + 137^2)/2), or about 127.5
>MHz.

The "middle of band" is best calculated as the geometric mean of the
band limits, so it's sqrt(118 * 136) = 126.68 MHz. If an antenna is
resonant at 126.68, it will be down the same amount at 118 and 136
(if the resonant peak is symmetric).

I've never seen root mean square used in frequency calculations, and
can't see how it's useful here.

Well, here's a couple of hints:
The North Star is within a couple of degrees of North, certainly close enough for HF antenna aiming.

GPS receivers will do a pretty fair job of locating a point due north of a reference, say your antenna, where a mark may be made to aim at.

The position of the sun with respect to your location is published every spring and fall as part of the solar outage of satellite communications information. Look up the time when a satellite with the same longitude as yours will be occluded, and the sun will be due south at that time that day. Mine occurs at 12:45 this week. Put out two stakes in a N-S line.

Anyone who chooses to live on top of the magnetic pole gets what they deserve, but pity the chaps up at CFS Alert radio monitoring station. They are so far north, the geosynchronous satellites are 10 degrees below the optical horizon.

Hi John,

The page you offer above appears to go to sufficient detail to already
answer your question.

It is not, by the way, a means to tune out 60Hz interference - except
insofar as the interference is separable by the two feed antennas to
the goniometer. They would have different coverages and it is
presumed in this instance that one exhibits the interference in
greater amplitude (an imbalance) or in a phase shift (that is not seen
in the underlying signal; again, an imbalance), either of which allows
the adjustment of the coil rotor to offer a phase rejection to the
summed output to the receiver.

A simpler treatment (especially the math) may be found in the
discussion of synchros, servos, and magnetic amplifiers.

I`ve looked st Terman and some other references because Chip`s statement rang an old bell. But all I found was Bailey`s graph and text. Bailey`s solution obviously depends on where he ends his near-field. The slope is at a point on a curve, or the point which best represents the "trend" of the curve.

I am not going to ask Chip for confirming data :^).

Reminds me of a cartoon. A customer is sitting in a restaurant,
and the waiter has just brought out one of those covered serving
platters that they use in oh-so-elegant joints, and announces,
"Here is your Peking duck," while the duck has lifted the edge
of the dish cover and is peeking out.

Well, score a half-point for me on that one - I got the three
syllables, but I've been putting the accent on the first:
Poe' puh lish. I think if you'd spelled it with the two l's,
I'd have got much closer. :-)

And then there were the two carpetbaggers in Natchitoches, LA, who
weren't sure of the pronounciation, so they went into a fast-food
joint, and asked the counter kid, "How do you pronounce the name of
this place? And please say it slowly, so we can get it." And she
says, "Buuuuuuuurrrrrrrr-Gerrrrrrrr Kinnnnnnnnnnng."

Hi Richard:

I don't necessarily doubt Chip, I just cannot find any reference to the 1/r energy or power dependence in the near-field.

My opinion at this point is that defining a general rate of energy decline in the near field is somewhat nebulous because the extent and field behavior in the near field is a function of frequency, antenna size, antenna type, geometry, etc, etc. The far-field is easy.

>k5qwg
>>

Hi Bob,

This is one of the popular ways, and the source of the last infection
that hit here. What Roy discusses goes beyond MS typhoid mary
software and may be related only where the original infection then
induced this characteristic.

There is absolutely no need of your e-mail client nor even an e-mail
server to start an e-mail attack FROM your machine. E-mail is
insecure from the get-go. You may not succumb to the attack that hits
Outlook Express with the regularity of a swiss watch; but that does
not mean you are free of e-mail related outgoing activity (unless you
never open nor run attachments nor visit sites that can induce
execution on your system). A fire wall is the appropriate detection
and interdiction mechanism.

As a sidebar to the browser debate (and focusing on sites that may
execute programs through Java Script), it serves to mention that
security issues with IE, OE and other MS products has a solution:
disable the Java Script function of your browser (and I seriously
doubt the last vector of infection has performed this obligation).
This advice, from Microsoft, cynically emasculates its own product,
and yet we have a correspondent here who embraces the insecure
configuration by bowing to the "market" demographics. IE dominates
the market, so the rationale goes, while conveniently neglecting to
observe IE/OE also dominates the occurrences of infection. The irony
here is that this correspondent is arguing the insecure configuration
is speedier, better, and expected by all and that to disappoint them
with older, secure designs would prove to be a disservice. Actually
this is simply the appeal to inertia and the inability to provide

reliable service; and instead simply offer its illusion with the imprimatur of the tainted MS logo. The argument almost conforms to the old saw that "What is good for IE, is good for the Internet." In the past, that was meant to be General Motors, who over time abandoned their customers, their heritage, and their market share. As with the ENRON/Anderson debate, we live in a time of denial.

None of this is speculation, weekly headlines reveal this factually. Microsoft admits it with its own warnings, patches, and configuration details (even if with faint breath in the face of counter assertions from its marketing department). Chairman Bill has even mandated attention to Security is an issue in Microsoft.

> Actually, it's 135.975, 720 channels total.

You must be somewhat behind in your news. The top MHz. (136 to 137) was
inserted into the VHF COM band about three years ago. The top of the band
IS 136.975. 760 channels total. Go look at any transceiver
manufacturer's page and you will see that they are advertising 760 channel
radios, not 720.

>
> The "middle of band" is best calculated as the geometric mean of the

> (if the resonant peak is symmetric).

Brain fart. Middle of the band is sqrt(118*137), or 127.1. Was thinking
about a totally different problem when I wrote that equation -- obviously.

Jim

>Brain fart.<

Being a persistent old fart with half a brain, I decided to call the regional FAA office at MHT this morning and ask about antenna polarization. After a few pings and pongs, I connected up with a helpful chap (also named Jim) who was pegged as the local guru for area radio sites. He never heard anything about circular polarization for Com. sites and seemed puzzled by my question. Said there may be a test bed or two out there somewhere (possibly in your part of the world), but if I want to hear ground stations in the Northeast Corridor, I'd best stick with good old linear vertical polarization 'cause that's what the FAA is using.

Shoot me or call me a bad name if you like, but that's just what he said--and it corroborates totally with what I see on the rooftops of various area facilities.

Hey, anybody that does the research and has somebody they believe to be right, I'm more than willing to listen. I based my words on two people who have never given me a bum steer, and there is every chance (like me) they are very conversant with what goes on in the AIRPLANE and were given bad advice themselves about what goes on on the ground. It happens. Next time I'm down to Sac Metro or over to Reno, I'll look myself at what is on top of the tower. Since the radio bay is two floors below the tower cab, I'm willing to bet what is on top of the tower is the antenna farm for the tower.

Hey, I just thought of something...and I don't have time right now to confirm it. Anybody who lives LINE OF CLOSE SIGHT from the tower (to eliminate as many reflections as possible) and has a spectrum analyzer or service monitor with S-meter, rig up a dipole a few wavelengths above the ground and see if you get a decent null when the antenna is horizontal referenced to vertical. Even better, get a friend with an acro airplane to take you up and put the sucker in knife-edge and note the noise on the signal {;-)

No. All you need is a connection to the Internet. Depending on how you've set up your system, what operating system you're using, how you've set various options, and so forth, a hacker might be able to put a program right onto your computer without you knowing anything about it, and without using your email program, browser, Outlook, or any other normal Internet connection program, and without sending you email or your looking at a web site. It can be done any time you're connected. Some of the programs that are implanted this way send out worms. Others are used to remotely send spam, anonymously send messages of the hacker's choice, participate in denial-of-service attacks, send your personal information back to the hacker, or basically anything else the hacker wants to do. This isn't a vague, never-happens kind of thing. My firewall records several attempts to get into my system every day. Roughly 30% of the spam I receive comes from an "open relay" -- a system where the hacker had planted software to send out the spam, unbeknownst to the user whose machine actually sent it. It's happening all the time. The only way to protect yourself is with a firewall. Like locking your door, even that isn't guaranteed to keep out a determined hacker. But like other thieves, they'd rather rob the easy marks instead, so it keeps the vast majority of them at bay.

More and more people are getting DSL and cable connections, which greatly increases your vulnerability, since you're connected to the Internet whenever your computer is on, not just when you've connected with a modem. Also, a lot of ISPs give you a static IP address with a DSL connection. What this means is that once a hacker puts something onto your system, he or she knows exactly where to go to access the implanted program.

Folks, the Internet is the Wild West. There's no law, so you've gotta carry your own 6-gun. Nobody's looking out for you except you. There's a great deal of good information about this on the Internet. It would be well worth your while to spend a couple of hours educating yourself about how to keep yourself relatively secure in this environment. A search on "firewall", "open relay", or "back orifice" would be a good place to start.

It sounds like what you want to do is to feed a resonant dipole with ladder line, matching the ladder line to the dipole at the dipole's feedpoint. This is ok, you could do it with a 9:1 balun, but why would you want to? Your rig is probably designed to work into 50 ohms, so you'd have to transform back from 450 to 50 or so at the rig end of the line. Instead, just feed the dipole with 50 or 75 ohm coax. Unless you've got an exceptionally long run of feedline, the difference in loss will be negligible. And you won't need a tuner -- you can connect the coax directly to your rig. You might want to use a 1:1 current or "choke" balun at the antenna feedpoint to prevent current on the outside of the feedline.

If, on the other hand, you want to operate the dipole on multiple bands, the impedance will be near 73 or so ohms resistive only on one band. On the others, it'll be wildly different. A match would be good on only one band, but nowhere near right on the others, so there's no point in trying to match the line to the antenna. Just let the transmission line have a high SWR. Ladder line is an appropriate way to feed it, since its loss is low when it has a high SWR (at least when dry). So if that's what you're trying to do, just connect the 450 ohm line directly to the antenna, and let the tuner in the shack take care of matching to the rig.

Last time I tuned in, a group of credible Italian hams were getting set to actually run some reasonably well controlled and documented tests on a real EH antenna. What happened to that? If it hasn't taken place, does anyone know when it will?

I've tried this on 40m. Worked pretty well. Maybe 4-5 db's worth?? The f/b ratio was about 15-20 db's worth. Quite noticable. I can't remember the spacing I used. You would have many spacings that could work ok, but will vary the gain, etc. With mine, I changed feedlines to steer the array. Some have used L/C phasing units with good success. But you can't stack the antennas, you have them set up like a yagi. You could stack them, ala Lazy H, etc, but you need a transposed feeder between the elements. Most that run these use ladder line. With the ladder line it's simple to twist the line for the top element for the transposed feed. I fed mine with coax, and used switches, etc. I think it's easier to run them parallel like a yagi. Also the whole antenna is up in the air better than a stacked pair with a lower bottom element. MK

Well, ok, it worked I suppose. A couple of weekends ago I tried checking into the Maritime Mobile Net on 20m. The controller in Arizona couldn't make me out but a fellow in Florida picked me up and relayed me in as a checkin. That was at 100w on a TS-120s and the antenna was hanging from the ceiling fan in my room. I didn't have a chance to get a signal report. Florida was coming in at about 5-7/ 9. The down side was that my transmission was getting into the phone big time. I'll have to use lower power, or find a better spot for the antenna when I make a better version. Might even try it out at field day for a hoot (if the rest of the guys don't hang me up in it's place first), but they are a pain in the butt to tune, even the simple one I tried.

That's an EH... not a CFA by the way. I'm tempted to make the "Coffee Can" version a guy has on his web site for a laugh some time :-)
Just can't stomach drinking that much coffee in a short period of time ;-)

Hi Richard,
I don't have that particular book, but I'll see if I can track it
down. In the mean time, I'll pose a couple of questions, and throw out
a possible explanation for the 1/r falloff.

Is the graph a compilation of measured data? If so, what two antennas
were used in the measurements? What was the smallest distance between
them?

The reason I ask is that if the two are similar types and have similar
sizes, then the measurements may include additional effects. The first
is a reduction in the received power due to strong coupling between
the antennas. This occurs when radiation is scattered from the
receiving antenna back into the source antenna, changing the source
antenna's impedance. Does this change the power radiated by the source
antenna? At the risk of starting a whole new sub-thread - possibly.
Second, when measuring near fields, the receiving antenna ideally
should be small enough that the fields emitted by the source antenna
are not changed by the presence of the receiving antenna. A fairly
large receive antenna (e.g., a half-wave dipole) could certainly
modify the field distribution. Third, as Richard C. points out, the 2
antennas are not point sources relative to each other and certain
sections may react more strongly than other sections.

All these effects are related, but the bottom line here is that the
1/r variation in received power may be a manifestation of them.

73,
Bill N3WK

Arnaud Thopiteau wrote:
"I`d like to create a microwave beam, 2m in diameter at 100m length, 9600 Bps, using the least size, power consumption, and cost."

You could do this at 6725 MHz using an 8-ft dish, spaced 400 feet from your target to get a first Fresnel zone spot 8 feet in diameter. It isn`t cheap. It would take two microwave T/R`s and two 8-foot dishes for full duplex operation. You could multiplex your microwave for 600 channels each carrying 9600 bits per second with SSB multiplex FMed on your carrier and each of the voice channels supplied with the appropriate modem. Or, you could use all digital modulation and equipment.

For a single inexpensive channel, I`d use 9600 bps modems. on a cable if possible, through wireless in space, if not. Optical transceivers could be used with the modems if needed. It is sure to be cheaper than microwave.

> for 10 bucks. I guess its one of those 'Inverted L' kinda of antenna.

Hi,

If it's $10, then you might as well buy it. If it were to cost much more than that, then it wouldn't be worth it. Remember that it is *just* wire and some fairly obvious hardware.

Portable SW receivers don't usually need very much signal to overload - you might need an attenuator depending on the design of the radio when using an outside antenna. Some portable radios have an attenuator switch on the back close to the whip.

Most of those sorts of portable SW radios work pretty good with just the built-in whip. Is your residence not made of wood ? Do you detect better signals next to those cold windows ?

One advantage of using an external antenna is that the whip stays folded up and safe (as opposed to bent), especially when in bed listening to BBC sports anouncing the scores (helps me to go to sleep).
"Manchester 2, Womanchester 1.
Flogbottom 4, Bot Floggom 2.
Chesterfield 3, Hallway Table 2..."
...yawn... ...zzzzzzzz... <out>

> ...MFJ Antenna preselector...

The one with the tuning knob and assorted switches ? Adding that to a digital radio is a bit like having a nice car with the gear shifter mounted on the roof. Everytime you conveniently punch a button to bring up another preprogrammed channel, you then have to fiddle with the preselector to bring the signal up. Gets tiresome very quickly.

I wouldn't bother unless you proved to yourself that you needed it. It can really slow you down when browsing around the bands. At least, have a way to bypass it. You probably won't use it 95% of the time.

> the SONY AN--LP1 seems to be the best antenna
> but not available in the USA at the moment.

The Sony is (IIRC) an untuned active antenna. It has a switch to insert a filter, but it is basically wideband and doesn't distract from the radio

tuning.

Is it still manufactured ? Sony might not sell it in the USA, but I'll bet there are a hundred companies bringing them in from overseas markets (gray market). My ICF-7600 came from the Middle East to NYC where I bought it. Pick up a SW or Radio magazine and check the ads in the back if you want that antenna.

> My problem here is... the connectors from the Preselector,
> are co-axial..or whatever to the radio. But my portable has
> .. a MINI Plug for..."Ext Ant". How do i connect that output
> from the preselector to my radio.

Mini plug probably = 1/8" mini ("mono", not stereo of course). The MFJ probably has an SO-239 that accepts PL-259 (big threaded socket). I don't believe that Radio Shack has an adapter or a cable directly from one to the other - better ask (You got questions, they make up answers...). You have to learn to solder sooner or later, so you might have to make your own cable sooner than later... Or simply dispense with the preselector for now. Leave it until you know you need it.

To connect the radio to any outside antenna, purchase a prewired cable from Radio Shack with a 1/8" mono plug on each end. Get a long one. Then cut it in half and strip the wire ends. Now you have two cables that you can connect to various antenna projects and plug into your portable radio.

> Secondly.. apart from lightning and static.. will it
> damage the sensitivity of my Sony Portable in anyway !

Shouldn't - that jack is intended for external antennas. It is NOT intended for lightning. Disconnect when not in use. Don't use during storms - too much static anyway.

> "passport to world band radio" and "ARRL Handbook"

Oh my gosh, you're all set. Great books ! Just keep in mind that even the most complex and advanced theories created by Man pale in comparison to the complexities of the real world. Keep an open mind - but don't let your brains fall out.

Good luck.

The spacing is 8.33 kHz, although the transition is going to be a slow
process, and as a consequence the top of the band is even higher.

The majority, still come in as attachments. I think the writters get a
certain perverse pleasure in having the users "do it to them selves"

> NAV checks only the outgoing email that you intentionally send, and
> downloads from web sites. The common worms send email messages without
> using the browser, and without your knowledge -- and without NAV's
> knowledge.

It makes far more sense to check the incoming mail.

The virus makes use of "ports" on the machine, rather than the browser, or
mail program, although it may (and probably does) use the address book, or
it will select the addresses of all unanswered mail (not sure why any one
would want to do that)

> And your system can contract them from places other than the
> email and web sites that NAV monitors. If you don't have a firewall, a

> anti-virus program being the wiser. That worm can then send infected
> emails to others without using your browser, again without the
> anti-virus program knowing about it.

I've set here and watched the firewall report a probe checking the ports on
the computer, going right in order. When it didn't find any, it started
over. Some one has installed a termite on my ISPs server that they didn't
even know they had.

>There are a lot of firewalls

> notify you when the worm sends infected email to others.

>
Zone alarm is available free, or you can pay a small fee for the commercial
version. It is a good investment.

No, I have no interest in the company, but I have the product installed
(with license) on all the computers here.

Actually, and Richard explains it very well...this is one of those mistaken ideas that is believed in strongly.

It is true that MS and IE are prime tartets for the Script, Java, and attachments used to spread viruses, but as viruses get more sophisticated, they don't have to use the "let the user do it to themselves" approach and there are some really mean and capable ones around.

Besides being very easy to write, both worms and viruses are now available in a "do it yourself kit" that some kind soul has provided on the net. This means that the "Script kiddies" can now use a cook book approach for some stuff that with a little manipulation can become really nasty.

It is relatively easy to find a computer attached to the internet (the ones attached to cable modems are particularly vulnerable as they are on all the time and use the same IP which makes finding them and getting in easier). The user with malicious intent, merely finds an open port on said machine and it basically becomes his!
There are many ports on a machine and I have (as I said in another post) set here and watched a program start right through the list of ports on my machine and when it didn't get in, it started over (I had over 500 tries in one day)
Once in an open port that user can do almost anything the owner can.
Actually, in most cases they not only can do any thing the owner can, but many things the owner didn't know was possible. They certainly wouldn't try if they did. <:-))

Think about that for a little while. It can make a lot of converts for using firewalls.

I wanted to show how easy it is to get into an unprotected machine, but I'm not going any farther in providing information on a "how to" basis. <:-))
Just to say that it is very easy to get into the unprotected machine that is

on all the time, or that has a static IP.

BTW, my degree is in CS, I worked in industry as a Sys Admin, then Developmental Analyst (fancy way of saying programmer), and finally a project manager where the projects required FDA validation, prior to retirement.

I went back to school at age 47 (after 26 years as an instrument man) to get my degree which I completed in three years. I was picked up on a graduate assistantship and started into my Masters in CS, but fortunately was offered a very good job half way through the first term. I retired 6 1/2 year later. (It's a good profession<G> if you can stand the long hours, two or three calls per night...and a bit of travel where you never see the out of doors, except between the airport and destination.)

BTW, as a GA I taught 5 classes with 195 students and took two classes which were "The Design and Analysis of Algorithms" and "Digital Image Processing".
The first ended up using five level simultaneous equations for best case, worst case, and average case sorts. The second started with Fourier Transforms (not the Fast Fourier) and by the third week was using Matrix Algebra ...and the PHDs said not much math required.<LOL>

Any one not using a fire wall and not having picked up a virus yet is more than a little lucky. I use both Norton for incoming and Zone Alarm Pro in conjunction.

I mentioned the 500 plus port probes, but I didn't mention that I received over 250 viruses and worms last year. So far this year I have received a even dozen, but these 12 were far more viscious. None got through.

4514. Antenna Testing (receiving)

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-05 05:22:24 UTC
From: Ed Laughery <laughery@bellsouth.net>
Message-ID: <dsYg8.617$tg2.81591@e3500-atl1.usenetserver.com>
Source record: 147352

Hi

So you build a great new antenna (receiving) - the final test is obviously - hook it up and listen. But is it better vs your last great experiment? How do you go about performing a true instrument test of the antenna, homemade balun (easy to construct but was it close to a proper 9:1?), coax feed, sig-to-noise, pattern, etc. Any and all explanations will be greatly appreciated.

Regards
Ed

4515. Scanner Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-05 05:23:28 UTC
From: Bruce Nolte <brucenol@abs.net>
Message-ID: <3C845650.DD1D7195@abs.net>
Source record: 147353

Well, I decided it was time to drop my tower for service due mainly to a terminally sluggish 35 year old Ham M Rotor, but while the tower is down, I have several other items I would like to address. One of these items is a side-mounted scanner antenna, which I brought at Radio Shack several years ago for use with my scanner, and also found useful as an omnidirectional TV antenna, when mounted to a splitter. It is a cheap design using steel hardware and only six elements, and has corroded to the point of utter uselessness, except possibly as a dummy load.

I would like to replace it with a more robust design. I made an attempt to build one this morning out of some scrap 5/8 aluminum tubing and 3/8 thick aluminum plate, but with my current tooling I was unable to drill the necessary 5/8 diameter holes at the required 30 degree angle neatly enough to retain the tubes securely. My idea is a 12 element discone, with 48 inch diagonals and 32 inch horizontals, 6 of each. I may also decide to make it smaller and use a 54 inch whip on top to extend the range into the 50 Mhz range. Besides the difficulty of drilling large holes at an angle into Aluminum, the other problems I forsee are perhaps corrosion, and limited response at high frequencies (~800 Mhz) due to the large element diameter.

I am also considering buying a new antenna, but so far the Radio Shack piece of junk is the only thing I can easily obtain locally. Can anyone point me to a suitable design that I might be able to construct fairly easily, or a good source for a decent, but reasonably priced (up to about $75.00 or so) commercially made antenna I might be able to find in the Baltimore area, or get on order within a couple of days.

> DSL connection.

Most cable and DSL companies use static IPs (Addresses) so they can keep
track of their users. They pretty much have the ability to track where
their users go, and what they do while on line. Several have been caught
installing monitoring programs that keep track of internet usage.

> What this means is that once a hacker puts something
> onto your system, he or she knows exactly where to go to access the
> implanted program.
>
Some of these programs are smart enough to go visit specific web sites, or
newsgroups where they can check for updates to their payload.

This means what sat on your machine and maybe reported your financial status, or visits to the more seamy side of the net can be changed at a moments notice to send out anything on the computer to any one in the address book/list. It might even send out some of the pictures you were looking at to the people in your address book and they will have your name on them. Or...It just might destroy all of the information on the computer and even create some hardware damage.

> Folks, the Internet is the Wild West. There's no law, so you've gotta

I would add the following suggestions after checking the above:
Go to the following "reputable" sites and have them evaluate your site.

Privacy dot net http://privacy.net/ is a consumer Information Orginization that will do a system wide analysis for you.

Shields Up, is anoter Internet Security Testing Site.
https://grc.com/x/ne.dll?bh0bkyd2
>
But as Roy has stated so well, there are no gurantees and running an unprotected computer is like publishing your SS#, and any other information you keep on your computer in the daily newspaper.

You could come into the computer room in the morning and find your screen saver has been changed to the front page of a porno site. Nice for the kids to find. ...

These people depend on the average user not installing fire walls. They also depend on them believing that if they don't use Windows, MS Outlook, or Outlook Express they are safe.

It's true these are the most targeted, but no system is bullett proof and no system connected to the net is entirely safe.

The best bet is to get a good firewall, a good virus protection program, and do not leave the computer hooked to the internet when not using it. Don't blindly follow links. They can take you where you don't wish to go and leave the gift that keeps on giving, don't open attachments even when they are from some one you know without first verifying that they sent it intentionally.

Hi Ed,

Maintain a log of your stations. Compare logs.

Or to perhaps trim down the process, select several representational
stations and log them. Also note conditions, especially those that
affect propagation, or use the SINPO code. The WWV(H) stations are
suitable markers and would represent a consistent but modest (by
commercial standards) signal for clear channel conditions.

Find an old Hy-Gain Hy Tower.
If you are over good ground you will be able to operate 160,80,40,20,15 with excellent results.
Or build a similar antenna.
It uses the same principle as multiple dipoles connected to a common feed.
The one "closest" will radiate the most.
Keep your excellent ground system.
Build a vertical antenna with multiple stubs so that each stub is resonant for a given band.
Connect one feedline.
In my opinion this will work much better than a Butternut (have owned/used both the Butternut/Cushcraft/Hytower verticals) as well as have built shortened helically wound ones.

In my experience I have found the following:
Use the longest radiator you can. Even if you can get a short vertical to tune it won't receive worth anything.
If you must use traps be sure they are top mounted. A coil at the base eliminates much of the current in the antenna.
Use at least eight radials for the longest frequency desired. The efficiency with more than sixteen vs the ideal 120 is not worth the effort involved.

Due to the lower radiation angle with the vertical properly grounded your ability to work DX will be greater than that with a dipole unless the dipole is >1 wavelength high. That assumes that your not clobberred by QRM as the vertical will have no directionality.

Best wishes,
Richard W9EEE

No sir. The idiots that proposed this scheme in Europe are trying to impose it on the rest of the world. The rest of the world ain't interested. If there is going to be a division of frequencies, it is going to be a binary split like the one that split the 100 kHz. channels to 50, then 50 to 25, and then if we need them, 25 to 12.5.

In actuality, the top of the band is really 136.99999999999999999999..., but for those of us with reason and sanity in our band plans, it is 136.975.

4528. Parametric equations for skin effects in practical transmission lines?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-05 09:14:53 UTC
From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <a622ip$ed0$1@slb4.atl.mindspring.net>
Source record: 147366

Question for the NG:

Using simple constants for the classical R-L-C-G primary parameters of a transmission line does not allow for the modelling of frequency dependent skin effects. It is well known that the largest skin effect frequency effects are on the series R and L parameters. Normally the shunt parameters C and G may be considered constant with respect to frequency when compared to the variations in the R and L parameters.

Currently I am looking for some fairly simple formulae to easily/quickly calculate skin effects on R and L for practical amateur radio HF transmission lines like the common coaxial cables and ladder lines used by radio amateurs.

I am aware of the of skin effect formulae derived from first physical principles (e.g. Maxwell's equations, etc.) as elaborated for instance in Chapter 4 of: Ramo, Whinnery, and Van Duzer, "Fields and Waves in Communication Electronics", Wiley, New York, 1965, and other such textbooks. Specific calculations of the skin effects using such derivations from first principles often requires the evaluation of Bessel Functions and/or the use of nomographs over certain parameterized ranges, etc... These complex formulations are fairly detailed and not amenable to dinner napkin, slide rule, calculator or back-of-the-envelope calculations.

I am looking for something simpler than those rigorous formulae, some simple ad hoc "fitted" parametric formulae.

An area where I have some experience with this kind of calculation is in the area of telephone twisted pair wireline transmission as practiced by the xDSL community which uses the following practical parametric formulae, documented in ANSI T1.417, "Spectrum Management for Loop Transmission Systems", Annex B: "Loop Information". In that document is shown two formulae for the series resistance R and inductance L per unit length as a function of frequency f. These simple parametric formulae are quite accurate and easy to calculate for typical lines:

1.) R(f) = (Ro**4 + a*f**2)**(1/4)
2.) L(f) = (Lo + Li*(f/fm)**b)/(1 + (f/fm)**b)

Besides the Ro and Lo, the two fundamental transmission line primary parameters involved here, there are only four other parameters required to predict the skin effect over quite wide ranges, namely: "a", "Li", "fm" and "b". These four parameters closely characterize the lines over the frequency range of zero to the double digit MegaHz. I don't know the "derivation" or original source of these neat formulae, most probably they were arrived at by some ad hoc heuristic method. If anyone knows of an

attribution for their source, author, or inventor I would be pleased to hear of those. Here:

"Ro" and "Lo" are the "classical" low frequency primary parameters, evaluated at or near DC, these are the static resistance and inductance per unit length respectively. "a" is a parameter chosen to fit equation 1.) to practical field measurements. "Li" is a measured high frequency inductance, and "b" and "fm" are parameters chosen to fit equation 2.) to practical field measurements.

For examples:

(1) AWG 26, plastic insulated, twisted pair copper cable modeled with the following parameters yeilds exceedingly good fits to measured data: Ro = 286.2 Ohms per kilometer, Lo = 675.4 uHy per kilometer, Li = 489.0 uHy per kilometer, with the parameters: a = 0.14770, fm = 806.34 kHz, b = 0.929.

(2) ANSI Category 5 twisted pair, used in high speed LANs, Ro = 176.6 Ohms per km, Lo = 1090.8 uHy per km, Li = 504.5 uHy per km, a = 0.05001, fm = 32.57 kHz, b = .705.

Now my question...

Does anyone here know of a source for formulae, perhaps 1.) and 2.) are sufficient for this use, and values of parameters for common amateur radio transmission lines. i.e. 50, 75, and 93 Ohm coaxial cables and ladder style window line or open wire line?

I'd appreciate any feedback...

Thanks,

--Peter K1PO

4532. Re: Parametric equations for skin effects in practical transmission lines?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-05 10:45:59 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C84A1E7.887E34A5@eznec.com>
Source record: 147220

When the wire radius is at least several skin depths, virtually all the current flows in a thin layer near the surface. The current density follows an exponential curve until it gets to an insignificantly small value. So for practical purposes, we assume that it has decayed to zero. With this assumption -- again valid as long as the radius is at least several skin depths -- we can further simplify by observing that the integral of the current density from the surface downward to an infinite depth is the same as for a uniform current density equal to the surface current density but abruptly ending at the skin depth. That is, if the current density at the surface is I and decays exponentially to zero as I*exp(-x/d) where x is the depth and d is the skin depth, then the total current is the same as for a current whose density is uniform and equal to I, but which extends from the surface down to the skin depth but not below. Of course, this observation is true only if the wire is homogeneous as well as being adequately thick.

Armed with these approximations, we simply calculate the area of the ring carrying this imaginary uniform current and multiply by the resistivity and length to get the resistance. The inside radius of the ring is r - d where r is the wire radius and d is the skin depth. The outside radius is r. So the area of the ring is pi*(r^2 - (r - d)^2) = pi*(r^2 - r^2 + 2rd - d^2) = pi*(2rd - d^2). d^2 is much smaller than 2rd because of the initial requirement that d << r, so the area of the current-carrying ring is about pi*2rd. The resistance of a wire of length L is then rho*L/(2rd) where rho is the resistivity of the conductor in ohms*length. (The RF resistance is r/(2d) times the DC resistance.) You'll find that the resistance increases as the square root of frequency, since the skin depth, hence the area of the imaginary conducting ring, decreases as the square root of frequency. Nasty math is necessary only if significant current extends either to the center of the wire or to a material of different conductivity than the surface material.

I haven't dealt with the frequency effects of inductance as much, since the effect is much smaller and can often be ignored. But in Walter C. Johnson's _Transmission Lines and Networks_, you'll find (ending on p. 79) a derivation showing that the internal inductance is 2d/r times the DC inductance -- just the reciprocal of the resistance factor -- when applying the same conditions as for the resistance calculation. As Johnson points out, the internal inductance is almost always a minor part of the total inductance, and the external inductance doesn't change with frequency. So over moderate frequency ranges the change is minor.

Combining the formula for skin depth with the formula for RF resistance, you get that the RF resistance per unit length = ~ sqrt(f*mu*R')/2 where

mu is the permeability (NOT relative permeability) of the wire and R' is
the DC resistance of the wire per unit length. Another way of expressing
the RF resistance per unit length is sqrt(pi*fmhz*mur/(10*R')) where
fmhz is the frequency in MHz and mur is the relative permeability of the
wire (1 for copper or other nonferrous metals).

From: Val <nishikeit@zilch.com>
Message-ID: <3C84A72E.4B498A05@zilch.com>
Source record: 147222

What kind of instruments do You have?
What kind of balun?

The easiest set up: A QRP SWR meter (bridge).
Broadband HF Balun.

Say the balun is 4:1. Obtain a 5W, 200ohm resistor.
(200 ohm = 50 ohm x 4). Attach the resistor across the
ouput of the Balun (disconnect all antenna wires).
Transmit 5W at any shortwave band into the balun. Is
the SWR= 1. Good. The Balun is 4:1. You can test on
each band You want to use to be sure...

Harder set: Narrowband HF balun. Same method, but use
correct frequency.

No QRP SWF meter available (>approx 10 W), or VHF:
Obtain a balun with a 100% known ratio (reference), e.g.
loan one from a friend. And it shall have the same
ratio You want the unknown Balun to have.
Connenct the 2 balanced ends ot the Baluns to to
one-anothe. Connect a 50 ohm dummy-load to the reference
balun. Connect a Hi-power (some 100W) to the un-known
balun. Measure SWR at TX end. 1:1 (or very near) = The
two baluns have identical ratios! In this case,
If NOT SWR= 1:1, You can easily calulate the real
ratio, concidering the ratio of the reference Balun
and the SWR reading!

Good Luck!
V.

Source record: 147225

Peter, you don't need formulae. They've already been worked out for you and incorporated in easy-to-use programs. You forgot to mention conductor proximity effect on balanced lines. Did you know close-spaced, air-insulated twin-lines have a higher loss than coax?

The following programs analyse transmission line performance for any complex terminating impedance, from power frequencies, via audio and carrier freqs, to UHF.

Enter dimensions of well-known products and compare with manufacturers' data, and with loss/freq curves in the ARRL handbook.

Check performance of SHV power lines stalking over mountainsides. Or of those olde-worlde, overhead, wide-spaced, porcelain-insulator phone lines. Yes, in 1900, you really could speak over the 400 miles of open-wire line between London and Edinburgh, long before the negative feedback line amplifier had been invented. Heaviside had already invented the distortion-reducing line-equaliser. He was the first true Hi-Fi enthusiast.

Sorry, programs deal only with copper, or perhaps aluminium conductors.

Dear people,

As you know I'm a student of TU Delft doing research in your patented technology. Because I'm know able to simulate such kind of structures, I have to design a dual-band Sierpinski patch antenna. The problem is that this antenna is very narrowband (1.5% or less).
What techniques are known for broadband matching such a Sierpinski patch antenna? What are your experiences?

Let me know, because then I can continue to finish my thesis, Rafael

The pronouciation is pretty obvious, it's just not the same as in
english/american :o)
Say bo-jo-lay (with the "o"s pronoucend almost as the "oa" in "boat") and you'll
be pretty close. There's just a problem with the "j" which must NOT be
pronounced "dj".

Another funny english pronounciation problem: nature and mature. Only the first
letter changes...

Peter, as for so-call ladder lines, the most accurate way of determining Zo
and dB per 100-feet is to measure the stuff.

It is clear manufacturers make no quality-control measurements except for
space travel - they just carry on making it to some incorrect formula they
forgot long ago. In their ignorance they probably use the ARRL bible
air-spaced line dimensions.

But the previously mentioned programs can easily be worked backwards to
estimate dielectric properties by inserting measured conductor diameters,
measured spacings and measured Zo.

BINGO! It will then be possible to predict Zo and dB/100-feet by using a
formula !

As Cecil will confirm, advertised 450-ohm line is a misnomer. If Cecil used
truly 450-ohm line he might have to change his recommended line lengths as a
replacement for tuners.

On the other hand, who cares about a couple of dBs more or less ? ;o)

Radio is the most inexact of all the sciences. Therein lies its mystical
beauty !

Arnaud Thopiteau wrote:
"But is it possible with tiny antennas? (2 inches diameter)"

Unfortunately, the smaller the spot at a great distance, the larger the antenna required for the necessary concentration.

If one requires a microwave illuminated spot limited to a small diameter at a great distance from where it is formed, a pipe or waveguide may be used to contain the wave to prevent spreading. The lowest frequency a 2-inch diameter pipe will permit pass is 19 GHz.

A small laser will retain collimation within a 2m diameter at 100m distance through a clear atmosphere.

Best regards, Richard Harrison, KB5WZI

Just count the number of turns. It is a FAR MORE accurate method of finding
impedance ratio than any measurement method. Can't go wrong !

I have some ground rods in the ground that I don t need now. Is there a way to extract them, other than excavation? This is copper clad steel 8 foot.

Worcester rhymes with Custer in England, Gloucester with Costa,
Towcester is pronounced Toaster, and there's a place near here called
Gotham (Derbyshire not Notts) that even the locals can't tell me whether
it's Goat-am, Got-am Goth-am or something else entirely.

Some years ago, a popular French wine sold in England went under the
name Macon Rouge. The way most English people pronounce it, a Frenchman
would have thought they were saying "my red c**t".

Oh, by the way, the Smith of Smith chart fame is actually pronounced
"Llanfairpwllgwyngyllgogerychwyrndrwbllllantisiliogogogoch".

Ed Laughery wrote:
"How do you go about performing a true instrument test of the antenna?"

Commercial stations measure the field strength in the target area. For shortwave that isn`t good enough. Propagation is too variable. So, commercial stations erect a standard antenna more or less alongside the test antenna for field strength comparison between test and standard antennas in the target area. How many db better is the test antenna than the standard antenna?

You could turn this around and compare received signals on the test and standard antennas. How many db better is the signal from the test antenna than it is from the standard antenna.

We couldn`t make meaningful receive measurements conveniently in a high-power transmitter site with a host of transmitters pouring out a megawatt of power in the same frequency range. But we were able to make good bridge measurements with a Hammarlund SP-600 as a bridge detector. We also couldn`t conveniently transmit from the target areas.

But, we could erect a standard antenna to compare our curtain antennas against, as received in the target area. Our standard test antenna was a three-wire folded dipole to match our 600-ohm transmission lines. It was at the same height as our curtain drivepoint. Then we measured and compared signals from the two antennas in the target area. No matter what the actual signal strengths were running at the measurement time, the difference between the antennas was a fixed advantage. We made many measurements and averaged.

Best regards, Richard Harrison, KB5WZI

My 450 ohm ladder-line measurements have averaged about 400 ohms with a VF
of about 0.9. That's what I presently use for estimations. 300 ohm ladder-
line came in about 265 ohms with a VF of about 0.8.

Why, take them out ? Just pound them down below ground level unless you want to reuse them, or need to remove them. Also you may want to try a pipe wrench, this helps in 2 ways first you grip the rodand spin it around in both directions with the wrench to loosen it up, Once it is loose leave the wrench on it and work it out while turning and pulling, watch your lower back on this one tho, depending on your soil I have seen people pull out 10-12' rods with a pipe wrench and the twist and spin technique. Good Luck

Microsmith will do that. You have a selection of transmission lines,
parallel and serial L/C combinations, and loads. The components are
variable so you can change them and observe what happens on the Smith
Chart.

Roy, Reg:

Roy, that explanation was a great help. Thanks for that feedback.

FYI... a little background on the ANSI Committee T1 transmission line models...

Operating high bandwidth (broadband) digital signals on public telephone plant is a non-trivial task. This copper based broadband signalling technology is generally referred to as Digital Subscriber Loop or "DSL" and tends to use very advanced coded modulation and other coding techniques to pack as many bits per second per Hz as possible, e.g. upwards of 10bps/Hz or more in very messy transmission and interference conditions. Some of the more recent DSL versions are known as HDSL (~1.5 Mbps), ADSL (~2-4 Mbps), VDSL (~50 Mbps), SDSL (~1.5mbps), G.SHDSL (~1.5mbps), etc... The committees are now approaching standards for Ethernet speeds, 10Mbps at varous distances. These digital modulations are sent over very long lossy cables with lots of interference aka cross-talk. Universally these techniques use application specific digital signal processing techniques, stressing very low power dissipation requirements.

A typical local carrier serving area (CSA) has maybe upwards of 2000 or more subscribers inside a radius of approximately 1500 Ohms. That's about 12,000 feet of AWG 26. Those individual AWG twisted pairs are bound together in binder groups of 50 pairs. There is substantial cross-talk between pairs especially at the higher frequencies. Imagine one signal with 49 hostile cross-talkers. The cross-talk can be foreign or self. Foreign is cross-talk from a different kind of DSL into the given DSL, and self-crosstalk is when a DSL cross-talks into it's brothers. The terminating resistances are around 100 Ohms, compared to the transmission resistances of up to 1500 Ohms, a very lossy environment. These technologies have to run "full-duplex", that is run both transmit and receive on the same wire pairs and successfully receive signals in the presence of their own transmitters as well as the cross-talkers. Duplexing methods in use are: Echo Cancellation (EC), Frequency Division Duplexing, (FDD) and Time Division Duplexing (TDD).

The public network standards setting groups around the world (ANSI, ETSI, ITU) who "bless" new proposed DSL technlogies for use on public loop plant cannot do so unless they can guarantee both performance and spectral compatibility.

Such guarantees are a messy techno-political business involving, among other things, lots of computer simulations. Computer simulations are mandatory, since before anyone commits to $5 - $20 MM for new VLSI dsp hardware, they want to know that it is going to work and that it has a fair chance of

becoming standardized.. To "prove in" each new proposed xDSL Standard modulation mode lots of these computer simulations must be performed and double checked. These simulations are generally done by the companies who voluntarily participate in the standards setting process, in the hope of generating business of course. This means many transmission computer simulations performed by competing companies technical folks performed over various lengths of copper pairs with various impairments added in the presence of mixed sets of hostile cross-talkers, etc. Additionally sometimes, out at the feeder-distribution interfaces there are bridged taps or open circuit stubs of varying lengths applied across pairs as well, these act as 1/4 wave "notches" which affect performance. Also diurnal and seasonal temperature variations cause the copper resistance to vary substantially. To say the least, these are generally very substantial and difficult computer simulations. The simulations are generally done on various simulated sets of "test lines". All participants in these simulations are companies, in competition with each other, e.g. Alcatel, Lucent, Broadcom, Globespan, etc... and to make progress without political-economic standoffs, they must first agree on a basic "platform" e.g. models on which they will do their simulations and cross-confirmations of simulations.

And so... the parametric formulae involving skin effect that I quoted in the earlier posting comes from some of that simulation work done for the ANSI Committee T1, and is documented in ANSI T1.417.

My interest in all of this is because I am interested in how far such work might be carried on into other transmission line areas and whether any of the computer codes developed for DSL evaluation could be easlily "migrated" to other applications.

Thoughts, comments?

Thanks again,

--Peter K1PO

Gary,
There isn't any ~one~ antenna that's the 'best' in
all circumstances, doesn't make any difference if it's
a 'CB' antenna or any other kind. Thre are only antennas
that work well for ~you~, in particular circumstances.
It depends more on how the antenna is situated and tuned.
Antenna manufacturers are like politicians, if you believe
anything they tell you, you're in trouble!

Rafael:

I don't know what *your* definition of broadband is, but generally...

The Smith Chart is thought of as a "narrow-band" calculator. It has no real application to broadband matching.

Use of the Smith Chart assumes that the reactances are all represented at a single frequency or very narrow band of frequencies. The Smith Chart is not really suitable for broadband calculations.

For broadband analysis and synthesis other, more sophisticated, tools are required.

For interest, just what is your definition of "broadband"? i.e. in relative terms what is the ratio of the bandwidth of interest to you say (f2 - f1) to the center frequency (f1 + f2)/2 ?

Best,

Papi wrote:
"What is the best (nnn-beam) base antenna out there on the market today for c.b. radios?"

Most places you want to communicate in all directions and would not use a beam.

Most places, except near polar regions, you are exposed to lightning.

The choice is then clear. The world`s best antenna is Andrew Corporation`s stainless folded monopole, cut for your 27 MHz frequency, and factory tuned for 50-ohm impedance at resonance.

It will safely ground out lightning strikes to the top of your grounded metal supporting structure, and receive well in all directions for years requiring no attention in most cases.

Best regards Richard Harrison, KB5WZI

>Was I right?

No....

You're assuming that noon in your time zone coorelates to solar
noon... This is not the case... The best way or fixing solar noon is
to put a stake in the ground... at about 11am, start plotting the
shadow of the stake every few minutes... You should see the shadows
growing shorter, then longer again... When the shadow is at it's
shortest, you'll have an indication of when solar noon occurred, and
the shadow will be pointing to the true north pole...

You MAY want to plot this out on a few different days, just to smooth
out any errors in timing/marking...

Dick wrote:
"As I am tired of changing the antenna, what would be nearly as good or better?"

On continually wet land near the sea, you will do poorly with low horizontal antennas. You can do well with vertical antennas. Dick has already done some of the right things. He put up vertically polarized antennas.

One good vertical may be enough. It needs to be well connected at all times with that good earth system. Surely there are times when the surface dries out, and then enough radials are needed. Chicken wire is bad according to Ed Laport. Cross connections between radials beyond the immediate tower area, where the copper needs to be sheets, is bad according to Ed. It only encourages eddy currents which increase ground loss.

If the vertical antenna would be used at frequencies where it is longer/higher than 5/8-wave, traps can be used to shorten it.

An efficient, wide ranging antenna tuner is probably needed.

Best regards, Richard Harrison, KB5WZI

Hi all,
I installed Zone Alarm and have been very satisfied with it. You say
you had 2 or 3 per hour? I had to shut off the notification of
attempts because of the volume of them. I had so many all I did was
click ok. Now I just make sure it is on and ignore it.
BTW, the reason I installed Zone was, when I was connected to the net,
and not sending or receiving actively, my computer was! I couldn't
figure out what program it was that was using my system without my
permission. After installing Zone I found out that my Eudora was
initiating contact with its web site. It took me 3 levels of customer
service to get to one that would admit Eudora had a feature that did
this. It then took another level to get to someone that would
instruct me on how to remove this feature. All the while telling me
to disable Zone so Eudora could work properly without Zone "bothering"
me!!! Well, I finally got the info needed to remove the problem.
Zone works great both ways, incoming intruders and outgoing
unauthorized contacts. Another BTW, for what it's worth. The last
place I worked had a strict policy of only using Microsoft programs or
programs that had been purchased by the company "Wonder Girl", the
bosses personal assistant. Fresh out of college and probably would
have become Gates' slave girl for free. Anyway, I told her I was
going to put my paid version of Eudora on my laptop because MS's
e-mail program is a joke. She was very upset until the next day when
one of the big virus strikes hit. I got virus e-mails from everyone
in and out of the company that used MS for e-mail. Later that same
day I confronted the "Wonder Girl" about why she sent me virus laden
e-mails. After she denied doing it I had her, she is the sys admin
after all, check the server and see who sent what. I then told her
that when Eudora asked me if I wanted to send out e-mails I did not
write, I just told it no. She also learned that day that once a week
is not often enough to update virus information!!! Oh yes, she did
also learn about firewalls too, although I heard afterward it was a
little late to help the network she set up. I hear they now hire
someone to operate the network. WHEW, way to much work!

The easiest way to find true north [or certainly close enough for antenna purposes is to use the old boy scout method. Find the outer most two stars on the big dipper. They are the non-handle end of the "pot". follow a line from those two stars upward from the pot's perspective [remember this varies by time and season of the year] and you will find the end of the handle of the little dipper. That is Polaris which is directly over the true north pole [with some minor seasonal variations] Drop an imaginary line from Polaris [North Star], straight down to the horizon and you are looking at true north.

You can find the magnetic variation of that from a geodetic survey map or navigation map. If you live in say Milwaukee [near where I grew up] you are in luck, for on a line roughly from Milwaukee to West Florida, the True and Magnetic Norths are almost the same. In Annapolis, where I sail, were are about 10 degrees off, so that a compass reading of 350 degrees is actually pointing you to true north. {In practice, most small boat navigators just stick to magnetic reading since that is how our boat compass's read...a GPS can usually read out in either. I have my GPS set to read Magnetic since I can match where I want to go with my boat compass.

In California, you will be in the opposite direction that I am. Find a friend with a boat, or go to a Marine store and any local navigation map will give you the nominal figure for your area...it will be right on the compass rose on the map.

I wrote that 19 GHz was the lowest frequency passed through a 2-inch pipe. Wrong!

2 inches is about 5 cm or the wavelength of a frequency of 6 GHz. As the diameter of the pipe only has to be 1/2-wavelength at the cut-off frequency, 3 GHz is the lowest frequency you could squeeze through a 2-inch pipe. Dang me!

Hi Rafael,

Build it with about 10 times the size you anticipated and treat it
like a 300 to 400 Ohm antenna. Review:
http://www.qsl.net/kb7qhc/antenna/fractal/Wide%20Band%20Comparisons.htm
However, I would add this has all been pointed out several times
before, and nothing has changed in the interval. What have you
accomplished in the past several months?

Hello Peter,

In reality I have to design for my thesis two equilateral triangular patch antennas resonating at 2.14 GHz and 1.95 GHz respectively. The bandwidth at each of these frequencies has to be
60 MHz. Thus 2.11-2.17 GHz and 1.92-1.98 GHz. Because the antennas will be used for mobile communication, the structure has to be planair and easy to made. Therefore I excited them with
microstrip line feeding. Because one section of microstrip line feeding the antennas at one of the edges seems to achieve narrow band behavior my tutor suggested me to design a broadband matching network
with different microstrip line sections of characteristic impedance.

Do you know other tools that are able to do that quickly using optimization??

Thanks already for helping me, Rafael

P.S. I was using a Smith chart program for plotting different kinds of points of impedance for different kind of frequencies and by impedance transformations these point could be transformed to the VSWR circle and therefore achieve wideband behavior.

What ever method you use for pulling it out, if you have time to
thoroughly water the ground around it, that will help. Ideally, put a
slow-running hose on it and let it run a long time. Days, if possible.

Use a car jack and a piece of chain. Put a clamp at the top
of the rod, wrap the chain
around it a couple of turns, and jack the rod out. It works
100%. Put some support
under the jack (a piece of 2 x 4 or something).

Hi Raymond,
many thanks for the explanation. Honestly I'd never tought about solar noon,
but just local noon.
Next time I'll follow your indications and will also see the difference
between the two methods.
I had to do the job again, because the wind has rotated the mast almost
90`!!

4585. Long square antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-05 18:10:02 UTC
From: "news.jonged.myweb.nl" <ed@jonged.myweb.nl>
Message-ID: <a631tegui1@cyan.nl.gxn.net>
Source record: 147174

The only place I have for my antenna is on my attic.
The ceiling (the floor of the attic) is made of alluminium strips with pressed cardboard tiles on the strips. The distance between the strips is 1 by 3 ft. At the moment I use a simple wire running half to one foot above the strips, length 16 ft.
I am planning to replace this with a square of wire that runs on the outer edges above the alluminium strips. The square is a rectangle about 14 x 16 feet. The idea is to keep it a closed loop. The two ends go to the 500 ohm antenna connection on my receiver and to ground on the same rig. I use a Icom IC-R75. (Yeah, I know, hang a wet wire on it and enjoy..:-).)

Could there be any disadvantages about this construction?
Are any tips recommendable?

Thnx, 73's!

>.......

Just a few observations: (1) My bugcatcher does exhibit
undesirable resonances on the upper bands (eg: 17 meters)
when I use a single jumper wire. By leaving the 40 m
and 20 m jumpers in place in addition to the one for 17 m,
the undesirable resonances are suppressed. (2) The mast
of the ScrewDriver (SD), in addition to shorting out
the coil with the fingerstock, also acts as a huge
shorted turn closely coupled to the unused portion of
the coil. This further "shorts out" the unused
portion of the SD coil and suppresses any resonances
excited by flux linkage from the top (active) portion
of the coil. (3) The length of the SD mast is crucial
to its operation and, as correctly surmised, actually
carries most of the radiative current. The longer
(higher) this is, the better.

But, but, but, that doesn't account for Daylight Savings Time. :-)

If you are just listening, I am not sure you would help your reception
that much by trimming it off any more. If you should decide to sell the
antenna, it would be easier to sell
if it is not shortened to something that is not useable to CBers or hams.
Just my .02.

I think Zone Alarm ought to be REQUIRED on online computers. It would
put a screeching halt to the burgeoning spyware industry.

During the peak of all the infection runs for Code Red .. etc .. they seem to peak out at between 3000 and 5000 attempts a day here mostly on Port 80 alone. The Port 137/138 game usually runs about 10% of that more during the whatma-jamma slurry peaks. That per the firewall and filter logs .. here.. Broadband 24X7 access is kinda a two-edged sword as has been properly noted.

Zone Alarm isn't available for OS/2 ..

As an additional note, in OS/2 you can use the command line form all in lower case please:

netstat -s

That will tell you what's connected to your box at that particular time. If it has established connections to what you don't want there, you can sure enough start looking for who, why, when and what to do about it. I have no idea how any of this works at command line levels in non-OS/2 systems, but the information, the techniques, are all pretty much the same for an in-depth study and learning project about all this mess.

Those running unprotected on the Web will have a lot of data to absorb once they begin to look, if they are up 24X7 and broadband!

The URL below that you may wish to look at gives a nice sobering BEGINNING display of what you face at all this and what to look for in Port and infiltation techniques:

http://www.robertgraham.com/pubs/firewall-seen.html

Bob Graham has done a nice job at presenting the first layer of the onion here! You should look at it if you've not been wild about thinking about these kind of thingees in my humble opinion!

Again ... visualize, if you will, that the whole Internet experience, has some very similar conceptual parallels to our ham experiences! You can think about filters, firewalls, and so on, much like we think about our beloved antennas here in this forum! In a way, impedance, SWR, and the like, all have a sort of a kind of a parallel experience when it

comes to exploring the medium there, as opposed to the medium we all know and love upstairs, kinda!

Wait until they combine arrival vectors similar to spread spectrum techiniques with internal polymorphic tools ... ;*(

The sad part of all this is that we spend more and more time on the technical parts of the IP medium game and less and less on antennas, talking to people over our medium, and love and care for those with problems we can solve if we share just basic information for all who need the help .. The couple hours a day wasted supervising a site now could much better have possibly spent working aluminum and talking to f0olks out there on RF!

;(

--> Sleep well; OS/2's still awake! ;)

Hi Jim, as you know I run an HS-1600 screwdriver with the
RV bottom extension so my bottom section is six feet. I
use a one foot section between my coil and my top hat.
With the top hat off, the screwdriver resonates on 10m
at the minimum coil rail.

I know that this subject has come up in the past, but I thought you might want to hear my most recent experience with UPS. I decided to try them again to see how they handled the shipments of my Carolina Cyclone antennas. Two of the shipments were damaged by virtue of slamming the packages down on one end SO HARD that they managed to ruin the decoupling collars. Now listen to (read) this one: The final shipment was packaged in 3" PVC pipe with plastic caps on each end. The ends were fastened with reinforced AND clear tape. The package was slammed down so HARD at some point that they lost the screwdriver component out of the package. Then the stupid idiots just re-taped the end that had been breached with the tube empty and shipped it on to its destination. DUH!
HOW do I know they slam shipments around so. HA! The Lexan coil cover was jammed down in the other end so tightly that it literally STUCK and can't be retreived--and that is with wads of newspapers on that end. The rest of the packing--and there was a lot--was missing along with the antenna unit. Now. To my mind, if a package weighs 10 lbs at point of departure, and it is 4' long, it arrives at some station along the way suddenly weighing less that 3 lbs. I would think something was wrong. It takes a blithering stupe to tape up an empty tube and ship it on. Never again will I ship UPS--I can't afford the b******s.
